1 Regular Problems

1.1 Problem 1

1.1.1 Part a

Define a map

$$\begin{aligned}\phi_{\text{ev}} : \text{hom}_{\mathbb{Z}}(\mathbb{Z}_m, A) &\rightarrow A \\ (f : \mathbb{Z}_m \rightarrow A) &\mapsto f(1)\end{aligned}$$

Then ϕ_{ev} is a \mathbb{Z} -module homomorphism, since

$$\begin{aligned}\phi_{\text{ev}}(nf + g) &= (nf + g)(1) \\ &= nf(1) + g(1) \\ &= n\phi_{\text{ev}}(f) + \phi_{\text{ev}}(g)\end{aligned}$$

But this forces $f(\bar{0}) = 0_A$ (where $\bar{0} : \mathbb{Z}_m \rightarrow A$ is the zero map), we have

$$0 = f(0) = f(m) = mf(1),$$

we must have $mf(1) = 0$ in A . So

$$\text{im } \phi_{\text{ev}} = \{a \in A \mid ma = 0\} := A[m].$$

It is also the case that

$$\ker \phi_{\text{ev}} = \{f \in \text{hom}_{\mathbb{Z}}(\mathbb{Z}_m, A) \mid f(1) = 0\} = \{\bar{0}\},$$

which follows from the fact that $\mathbb{Z}_m = \langle 1 \bmod m \rangle$ and $A = \langle 1_A \rangle$ as \mathbb{Z} -modules, so if $f(1 \bmod m) = 0_A$ then

$$f(n \bmod m) = nf(1 \bmod m) = 0$$

and so f is necessarily the zero map. So $\ker \phi = \bar{0}$.

We can then apply the first isomorphism theorem,

$$\frac{\text{hom}_{\mathbb{Z}}(\mathbb{Z}_m, A)}{\ker \phi_{\text{ev}}} \cong \text{im } \phi_{\text{ev}} \implies \text{hom}_{\mathbb{Z}}(\mathbb{Z}_m, A) \cong A[m].$$

1.1.2 Part 2

Lemma: If $x \mid n$ and $x \mid m$ then $x \mid \gcd(m, n)$

Proof: We have $x \mid km + \ell n$ for any integers k, ℓ . So let $d = \gcd(m, n)$, then there exist integers a, b such that $am + bn = d$. But we can now just take $k = a$ and $\ell = b$. \square

We claim that $\mathbb{Z}_n[m] \cong \mathbb{Z}_{(m,n)}$, from which the result immediately follows by part 1.

Define a map

$$\begin{aligned}\phi : \mathbb{Z} &\rightarrow \mathbb{Z}_n[m] \\ 1 &\mapsto [1] \pmod n,\end{aligned}$$

which we claim is an isomorphism. ϕ is clearly surjective since $\mathbb{Z} \rightarrow \mathbb{Z}_n$ is a quotient map and $\mathbb{Z}_n[m]$ is a subgroup of \mathbb{Z}_n , and if we let $d := \gcd(m, n)$, we have

$$\begin{aligned}\ker \phi &= \{x \in \mathbb{Z}_n \mid mx = 0\} \\ &= \{x \in \mathbb{Z}_n \mid x \mid m\} \\ &= \{x \in \mathbb{Z} \mid x \mid n \text{ and } x \mid m\} \\ &= \{x \in \mathbb{Z} \mid x \mid d\} \quad \text{by the lemma} \\ &= d\mathbb{Z}.\end{aligned}$$

Then by the first isomorphism theorem, we have

$$\frac{\mathbb{Z}}{\ker \phi} \cong \text{im } \phi \implies \frac{\mathbb{Z}}{d\mathbb{Z}} \cong \mathbb{Z}_n[m].$$

1.1.3 Part 3

Note: let $[x]_m$ denote the equivalence class of $x \pmod m$.

Let $f \in \mathbb{Z}^* = \text{hom}_{\mathbb{Z}}(\mathbb{Z}_m, \mathbb{Z})$, so $f : \mathbb{Z}_m \rightarrow \mathbb{Z}$. These are both \mathbb{Z} -modules generated by their identity elements, so such a map is determined by where it send $[1]_m$.

So let $f([1]_m) = n \in \mathbb{Z}$. Since f is a module homomorphism, we have $f([0]_m) = 0$, and in particular we have

$$\begin{aligned}0 &= f([0]_m) \\ &= f([m]_m) \\ &= f([1m]_m) \\ &= mf([1]_m),\end{aligned}$$

which forces $f([1]) \in \mathbb{Z}[m] = \{0\}$, so f must be the zero map and $\mathbb{Z}^* = 0$.

Note: $\mathbb{Z}[m] = 0$ because \mathbb{Z} is an integral domain, so $mx = 0$ forces $m = 0$ or $x = 0$.

1.1.4 Part 4

To see that \mathbb{Z}_m is a \mathbb{Z}_{mk} module, we define an action

$$\begin{aligned}\mathbb{Z}_{mk} &\curvearrowright \mathbb{Z}_m \\ [x]_{mk} &\curvearrowright [y]_m := [xy]_m\end{aligned}$$

This is a well-defined action:

If $[x_1]_{mk} = [x_2]_{mk}$ are two representatives of the same equivalence class, then

$$[x_1]_{mk} - [x_2]_{mk} = [x_1 - x_2]_{mk} = [0]_{mk} \implies m \mid x_1 - x_2.$$

But then

$$\begin{aligned}([x_1]_{mk} \curvearrowright [y]_m) - ([x_2]_{mk} \curvearrowright [y]_m) &= [x_1 y]_m - [x_2 y]_m \\ &= [(x_1 - x_2)y]_m \\ &= [0]_m,\end{aligned}$$

which shows that their resulting actions on \mathbb{Z}_m are equal.

This action yields a module structure:

- $r.(x + y) = r.x + r.y$:

$$[r]_{mk} \curvearrowright ([x]_m + [y]_m) = [r]_{mk} \curvearrowright [x + y]_m = [r(x + y)]_m = [rx]_m + [ry]_m.$$

- $(r + s).x = r.x + s.x$:

$$[r]_{mk} + [s]_{mk} \curvearrowright [x]_m = [r + s]_{mk} \curvearrowright [x]_m = [(r + s)x]_m = [rx]_m + [sx]_m.$$

- $(rs).x = r.s.x$:

$$\begin{aligned}[r]_{mk} \cdot [s]_{mk} \curvearrowright [x]_m &= [rs]_{mk} \curvearrowright [x]_m \\ &= [(rs)x]_m \\ &= [r]_{mk} \curvearrowright [sx]_m \\ &= [r]_{mk} \curvearrowright ([s]_{mk} \curvearrowright [x]_m).\end{aligned}$$

- $1.x = x$:

$$[1]_{mk} \curvearrowright [x]_m = [1x]_m = [x]_m.$$

$$\mathbb{Z}_m^* := \text{hom}_{\mathbb{Z}_{mk}}(\mathbb{Z}_m, \mathbb{Z}_{mk}) \cong \mathbb{Z}_m:$$

Define a map

$$\begin{aligned}\phi : \text{hom}_{\mathbb{Z}_{mk}}(\mathbb{Z}_m, \mathbb{Z}_{mk}) &\rightarrow \mathbb{Z}_m \\ f &\mapsto [f([1]_m)]_m\end{aligned}$$

ϕ is a homomorphism, as

$$\begin{aligned}\phi(f + g) &= [(f + g)([1]_m)]_m \\ &= [f([1]_m) + g([1]_m)]_m \\ &= [f([1]_m)]_m + [g([1]_m)]_m\end{aligned}$$

$$\begin{aligned}\phi([r]_{mk} \curvearrowright f) &= [[r]_{mk}f([1]_m)]_m \\ &= [r]_m \cdot [f([1]_m)]_m \\ &= [r]_{mk} \curvearrowright \phi(f).\end{aligned}$$

ϕ is injective, as $[f([1]_m)]_m = [0]_m$, then for any $1 \leq \ell \leq m$, we have

$$\begin{aligned}[f([\ell]_m)]_m &= [\ell f([1]_m)]_m \\ &= \ell [f([1]_m)]_m \\ &= \ell [0]_m \\ &= [0]_m,\end{aligned}$$

so f must be the zero map.

ϕ is surjective, since if $[\ell]_m \in \mathbb{Z}_m$, we can define

$$\begin{aligned}f_\ell : \mathbb{Z}_m &\rightarrow \mathbb{Z}_{mk} \\ [1]_m &\mapsto [\ell]_{mk}\end{aligned}$$

which makes sense and is well-defined because $\mathbb{Z}_m \hookrightarrow \mathbb{Z}_{mk}$, and the map is defined on the generator.

So we have the desired bijection. \square

1.2 Problem 2

We have the map

$$\begin{aligned}\pi : \mathbb{Z} &\rightarrow \mathbb{Z}_2 \\ x &\mapsto [x]_2\end{aligned}$$

which is a surjection and thus an epimorphism in the category $\mathbb{Z}\text{-Mod}$, and if we apply the functor $\text{hom}_{\mathbb{Z}}(\mathbb{Z}_2, \cdot)$ to π we obtain an induced map

$$\begin{aligned}\bar{\pi} : \text{hom}_{\mathbb{Z}}(\mathbb{Z}_2, \mathbb{Z}) &\rightarrow \text{hom}_{\mathbb{Z}}(\mathbb{Z}_2, \mathbb{Z}_2) \\ f &\mapsto \pi \circ f.\end{aligned}$$

The claim is that $\bar{\pi}$ is *not* a surjection, and thus not an epimorphism (in the same category).

To see that this is the case, we can simply note that $\text{hom}_{\mathbb{Z}}(\mathbb{Z}_2, \mathbb{Z}) = 0$ by part 3 of Problem 1, whereas $\text{hom}_{\mathbb{Z}}(\mathbb{Z}_2, \mathbb{Z}_2) \neq 0$.

For example, one can define

$$\begin{aligned}\text{id}_{\mathbb{Z}_2} : \mathbb{Z}_2 &\rightarrow \mathbb{Z}_2 \\ [x]_2 &\mapsto [x]_2,\end{aligned}$$

which is a nontrivial module homomorphism.

So any such f appearing must be the zero map, and thus $\bar{\pi}$ is also the zero map. \square

1.3 Problem 3

Let $f : R \rightarrow R$ be an endomorphism of R in the category of rings. We can then check that for any $r \in R$, we have $f(r) = f(r1_R) = rf(1_R)$, which says that f is given by right-multiplication by some fixed element $x_f := f(1_R)$, i.e.

$$\begin{aligned}f : R &\rightarrow R \\ r &\mapsto r \cdot x_f\end{aligned}$$

and so we can attempt to define

$$\begin{aligned}\phi_1 : \text{hom}_R(R, R) &\rightarrow R \\ f &\mapsto x_f := f(1_R)\end{aligned}$$

We can check that

$$(g \circ f)(r) = g(f(r)) = g(r \cdot x_f) = r \cdot x_f \cdot x_g,$$

which shows that in fact

$$\phi(g \circ f) = x_f \cdot x_g,$$

which reverses the multiplication. So the correct codomain is R^{op} , and we amend the definition:

$$\begin{aligned}\phi_2 : \text{hom}_R(R, R) &\rightarrow R^{op} \\ f &\mapsto x_f := f(1_R)\end{aligned}$$

By construction, ϕ_s is a ring homomorphism. If R is commutative, then $x_f \cdot x_g = x_g \cdot x_f$, which makes ϕ_1 a ring homomorphism as well. It remains to check that it is an isomorphism/

ϕ_1 **is injective:** We can check that $\ker \phi_1 = 0$ as a ring. To that end, suppose $\phi_1(f) = x_f = 0$. Then $f(r) = r \cdot 0 = 0$, so f can only be the zero map.

ϕ_1 **is surjective:** Let $x \in R$ be arbitrary, then we can define $f : R \rightarrow R$ by $f(1_R) = x$, so $f(r) = r \cdot x$. This is an endomorphism of R , and thus an element of $\text{hom}_R(R, R)$.

By the first isomorphism theorem for rings, we thus have $\text{hom}_R(R, R) \cong R$. \square

1.4 Problem 4

Note: Let $X^\vee := \text{hom}_R(X, R)$ denote the dual.

We have maps

$$\begin{aligned} \theta_A : A &\rightarrow (A^\vee)^\vee \\ a &\mapsto (\text{ev}_a : f \mapsto f(a)) \end{aligned}$$

$$\begin{aligned} \theta_B : B &\rightarrow (B^\vee)^\vee \\ b &\mapsto (\text{ev}_b : g \mapsto g(b)) \end{aligned}$$

$$\begin{aligned} f : A &\rightarrow B \\ a &\mapsto f(a) \end{aligned}$$

$$\begin{aligned} f^\vee : B^\vee &\rightarrow A^\vee \\ g &\mapsto g \circ f \end{aligned}$$

$$\begin{aligned} f^{\vee\vee} : A^{\vee\vee} &\rightarrow B^{\vee\vee} \\ h &\mapsto h \circ f^\vee \end{aligned}$$

We can now check that $f^{\vee\vee} \circ \theta_A = \theta_B \circ f$ as maps from A to $B^{\vee\vee}$. Letting $a \in A$, and $h \in B^{\vee\vee}$ (so $h : B^\vee \rightarrow R$), we will show that both maps act on h in the same way.

For notational convenience, write $\phi \curvearrowright h := h \circ \phi$. We then have

$$\begin{aligned}
(f^{\vee\vee} \circ \theta_A)(a) \curvearrowright h &:= f^{\vee\vee}(\theta_A(a)) \curvearrowright h \\
&:= f^{\vee\vee}(\text{ev}_a) \curvearrowright h \\
&= (\text{ev}_a \circ f^\vee) \curvearrowright h \\
&:= h \circ (\text{ev}_a \circ f) \\
&:= h(f(a)) \\
&= \text{ev}_{f(a)} \curvearrowright h \\
&:= \theta_B(f(a)) \curvearrowright h \\
&:= (\theta_B \circ f)(a) \curvearrowright h,
\end{aligned}$$

which shows that these actions agree, and thus the diagram commutes.

1.5 Problem 5

Let E be a free module over R an integral domain. Then E has a basis $\{\mathbf{e}_i\} \subseteq F$, so if $x \neq 0 \in E$, we have

$$x = \sum_i r_i \mathbf{e}_i$$

where each $r_i \in R$. Moreover, since $x \neq 0$, at least one $r_i \neq 0$, so let r_j denote one of the nonzero coefficients.

Now suppose x is a torsion element, so $mx = 0$ for some $m \neq 0 \in E$. We can then write

$$mx = m \sum_i r_i \mathbf{e}_i = \sum_i mr_i \mathbf{e}_i = 0$$

But by linear independence, this forces $mr_i = 0$ for all i . In particular, $mr_j = 0$ where $r_j \neq 0$. But this exhibits either m or r_j as a zero divisor, and since the only zero divisor in an integral domain is zero, we must have $m = 0$ or $r_j = 0$, a contradiction.

So x can not be a torsion element. But since $x \in E$ was arbitrary, E must be torsion-free.

For an example of a torsion-free module over an integral domain that is *not* free, consider \mathbb{Q} as a \mathbb{Z} -module. Then \mathbb{Q} is clearly torsion-free, since it is an integral domain and the same argument as above applies.

But \mathbb{Q} is not free as \mathbb{Z} -module. Supposing that $\mathcal{B} = \{\mathbf{b}_1, \mathbf{b}_2, \dots\} \subset \mathbb{Q}$ was a \mathbb{Z} -basis, consider $\mathbf{b}_1 = \frac{p_1}{q_1}$ and $\mathbf{b}_2 = \frac{p_2}{q_2}$. Then $\mathbf{b}_1, \mathbf{b}_2$ can not be linearly independent over \mathbb{Z} , which follows from the fact that

$$q_1 p_2 \mathbf{b}_1 + q_2 p_1 \mathbf{b}_2 = p_2 p_1 - p_1 p_2 = 0,$$

while $q_1 p_2, q_2 p_1 \neq 0 \in \mathbb{Z}$. \square

1.6 Problem 6

If A is a cyclic module over a commutative ring R , so we have $A = Ra$ for some $a \in A$. By Hungerford's definition, the submodule A has order $r \iff$ the element a has order $r \iff$ the order ideal $\mathcal{O}_a := \{x \in R \mid xa = 0\} = (r)$.

In particular, $ra = 0$.

1.6.1 Part 1

Since $(r, s) = (1)$, we can find $t_1, t_2 \in R$ such that

$$\begin{aligned} t_1r + t_2s = 1 &\implies t_1ra + t_2sa = 1a \\ &\implies t_1(ra) + t_2sa = a \\ &\implies t_2sa = a && \text{since } ra = 0 \\ &\implies s(t_2a) = a && \text{since } R \text{ is commutative,} \end{aligned}$$

which implies that $a \in sA$ and thus $A \subseteq sA$. However, we always have $sA \subseteq A$ for modules, so this shows that $A = sA$.

To see that $A[s] = \{x \in A \mid sx = 0\} = 0$, let $x \in A[s]$; we will show $x = 0$. Since $x \in A = Ra$, we have $x = r_1a$, and in particular

$$ra = 0 \implies rx = rr_1a = r_1(ra) = 0.$$

So we now have $rx = 0$ and $sx = 0$, and we can write

$$\begin{aligned} x &= (t_1r + t_2s)x \\ &= t_1(rx) + t_2(sx) \\ &= t_10 + t_20 \\ &= 0. \end{aligned}$$

So $x = 0$ and thus $A[s] = 0$. \square

1.6.2 Part 2

Suppose $r = sk$. Toward an application of the first isomorphism theorem, define a map

$$\begin{aligned} \phi : R &\rightarrow sA = sRa \\ x &\mapsto sxa. \end{aligned}$$

ϕ is well-defined:

This follows from that fact that $a \in A \implies xA \in A$ for any $x \in R$, so the codomain is in fact sA .

ϕ is an R -module homomorphism:

We have

$$\begin{aligned} t \in R &\implies \phi(tx) = s(tx)a = t(sxa) = t\phi(x) \\ x, y \in R &\implies \phi(x+y) = s(x+y)a = sxa + sya = \phi(x) + \phi(y) \end{aligned}$$

$\ker \phi = (k)$:

Suppose $x \in \ker \phi$ so $sxa = 0_A$; we'd like to show $x \in (k)$.

By definition $sx \in \mathcal{O}_a$, and by assumption $\mathcal{O}_a = (r)$, so $sx = t_1r$ for some $t_1 \in R$.

$$\begin{aligned} &sxa = 0_A \\ \implies &sx = t_1r && \text{since } sx \in \mathcal{O}_a \\ \implies &sx = t_1(sk) && \text{since } r = sk \text{ by assumption} \\ \implies &sx = s(t_1k) && \text{since elements in } R \text{ and } A \text{ commute} \\ \implies &x = t_1k && \text{since } R \text{ is a domain, so } sm = sn, s \neq 0 \implies m = n, \end{aligned}$$

which exhibits $x = t_1k \implies x \in (k)$ as desired.

ϕ is surjective:

Since $A = Ra$, we have $sA = sRA$ and thus $x \in sA \implies x = sra$ for some $r \in R$; but then $\phi(r) = sra = x$.

We thus have

$$R/\ker \phi \cong \text{im } \phi \implies R/(k) \cong sA.$$

Similarly, define a map

$$\begin{aligned} \psi : R &\rightarrow A[s] \\ x &\mapsto kxa \end{aligned}$$

ψ is well-defined:

It suffices to check that $\text{im } \psi \subseteq A[s]$ (since we will show surjectivity shortly), i.e. that s annihilates anything in the image. This follows from

$$s(kxa) = (sk)xa = rxa = x(ra) = 0,$$

since $ra = 0$ by assumption.

ψ is an R -module homomorphism:

We can check

$$\psi(tr_1 + r_2) = k(tr_1 + r_2)s = tkr_1s + kr_2s = t\psi(r_1) + \psi(r_2)$$

which follows because elements of R commute with those from A under multiplication.

$\ker \psi = (s)$:

Suppose $x \in \ker \psi$, so $kxa = 0$. Then $kx \in \mathcal{O}_a = (r)$, so $kx = rt_1$. Then

$$\begin{aligned} kxa &= 0_A \\ \implies kx &= rt_1 && \text{since } kx \in \mathcal{O}_a \\ \implies kx &= (sk)t_1 && \text{since } r = sk \\ \implies kx &= k(st_1) && \text{since } R \text{ is commutative} \\ \implies x &= st_1 && \text{since } R \text{ is a domain,} \end{aligned}$$

and so $x \in (s)$ as desired.

ψ is surjective:

Letting $y \in A[s]$ be arbitrary. We have

$$\begin{aligned} y \in A[s] &\implies x = t_1a, \quad sx = 0 \\ &\implies s(t_1a) = 0 \\ &\implies st_1 \in \mathcal{O}_a \implies \exists x \in R \ni st_1 = xr = x(sk) \\ &\implies st_1 = sxk \\ &\implies t_1 = xk && \text{since } R \text{ is a domain} \\ &\implies y = t_1a = (xk)a = kxa, \end{aligned}$$

so $\psi(x) = y$.

We can then apply the first isomorphism theorem

$$R/\ker \psi \cong \text{im } \psi \implies R/(s) \cong A[s].$$

□

1.7 Problem 7

Lemma: If M is a cyclic module over a PID, then M has exactly 1 invariant factor.

Lemma: Let A be a cyclic module, so $A = Ra$. If the order of A is r , so $\mathcal{O}_a = (r)$, then $A \cong R/(r)$.

This means that we can write $A = R/(a)$ and $B = R/(b)$, and a, b are the invariant factors of A, B respectively, and $M := A \oplus B \cong R/(ab)$.

Since R is a PID, there is unique factorization, so we can write

$$r = \prod_{i=1}^n p_i^{k_i}$$

$$s = \prod_{i=1}^n p_i^{\ell_i}$$

where we allow some $k_i, \ell_i = 0$ so that we can take the product over the same set of primes.

However, means that the elementary divisors of M are given by the multiset $L := \{p_i^{k_i}\} \cup \{p_i^{\ell_i}\}$.

The largest invariant factor d_1 of M is obtained from the elementary divisors by

- a. Forming the multiset L of elementary divisors,
- b. Selecting the highest power of each prime occurring, say $s_i := p_i^{\max(k_i, \ell_i)}$,
- c. Removing s_i from L ,
- d. Then letting $d_1 = \prod s_i$.

However, this process yields $d_1 = \text{lcm}(r, s)$ by construction, since

$$d_1 = \prod_{i=1}^n s_i = \prod_{i=1}^n p_i^{\max(k_i, \ell_i)} := \text{lcm}(r, s).$$

The next largest invariant factor is obtained by performing the same process on the remaining prime powers in L . However, we can note that after obtaining d_1 , we have $L = \{p_i^{\min(k_i, \ell_i)}\}$, since **there were only two choices** for each p_i occurring and we chose the copy with the maximal exponent.

But this means when we perform step (b) to obtain d_2 , **there is now only one choice**, and thus each $s_i = p_i^{\min(k_i, \ell_i)}$ and we have

$$d_2 = \prod_{i=1}^n s_i = \prod_i p_i^{\min(k_i, \ell_i)} := \text{gcd}(r, s).$$

Note: by construction, $d_2 \mid d_1$, since we are choosing from the same prime powers but with smaller exponents.

Since there were only at most two copies of each prime occurring in L , where one of them was chosen for d_1 and the other was chosen for d_2 , this exhausts all of the elements in L . But this means M has only two invariant divisors,

$$d_1 = \text{lcm}(r, s)$$

$$d_2 = \text{gcd}(r, s),$$

which is what we wanted to show. \square

Note: the indexing convention for d_i is opposite the usual one here, since we are choosing the largest invariant factor first, and so we have $d_n \mid d_{n-1} \mid \cdots \mid d_1$.

2 Qual Problems

2.1 Problem 8

2.1.1 Part 1

The claim is that every element in $M := R^n / \text{im } A$ is torsion \iff the matrix rank of A is exactly $n \iff$ the Smith normal form of A has exactly n nonzero invariant factors.

To see that this is the case, we can apply the structure theorem for finitely-generated modules over a PID. This gives us

$$M \cong F \oplus \bigoplus R/(r_i)$$

where F is free of finite rank, $R/(r_i)$ is cyclic torsion, and $r_i \mid r_{i+1} \mid \cdots$ are the invariant factors of M .

We thus have

$$M \cong R^n / \text{im } A \cong F \oplus \bigoplus R/(r_i),$$

which will be pure torsion if and only if $F = 0$.

But if we compute the smith normal form of A , we obtain

$$SNF(A) = \begin{bmatrix} d_1 & 0 & \cdots & 0 & \cdots & 0 \\ 0 & d_2 & & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots & \cdots & 0 \\ 0 & 0 & \cdots & d_n & \cdots & 0 \end{bmatrix}$$

where $d_1 \mid d_2 \mid \cdots \mid d_n$, and thus

$$\text{im } A \cong \text{im } SNF(A) \cong d_1 R \oplus d_2 R \oplus \cdots \oplus d_n R$$

$$\implies M = R^n / \text{im } A \cong \frac{R^n}{d_1 R \oplus d_2 R \oplus \cdots \oplus d_n R}$$

$$\cong R/(d_1) \oplus R/(d_2) \cdots \oplus R/(d_n)$$

where $R/(d_i)$ is a cyclic torsion module precisely when $d_i \neq 0$. If instead some $d_i = 0$, we then have $R/(d_i) \cong R$, which is a free R -module, yielding non-torsion elements in M .

But $\det(A) = \det(SNF(A)) = \prod_{i=1}^n d_i$, and so if $d_i = 0$ for some i iff $\det A = 0$ iff $\text{rank } A < n$.

2.1.2 Part 2

Identifying

$$R \times F = F[x] \oplus F \cong F[x] \oplus \frac{F[x]}{(f)}$$

where f is any degree 1 polynomial in $F[x]$, by the structure theorem we can pick a matrix $A \in M_2(F[x])$ with invariant factors $d_1 = 0, d_2 = f$. Then by the same argument given in part 1, we would have

$$(F[x])^2 / \text{im } A \cong \frac{F[x]}{(d_1)} \oplus \frac{F[x]}{(d_2)} = F[x] \oplus \frac{F[x]}{(f)}$$

So we can choose $n = 2$, and say $f(x) = x + 1$, and then just pick a matrix that is already in Smith normal form:

$$A = \begin{bmatrix} x + 1 & 0 \\ 0 & 0 \end{bmatrix}.$$

2.2 Problem 9

2.2.1 Part 1

Let M be a finitely generated module over R a PID.

Then

$$M \cong F \oplus \bigoplus_{i=1}^n R/(d_i)$$

where F is free of finite rank and $R/(d_i)$ are cyclic torsion modules (the *invariant factors*) satisfying $d_1 \mid d_2 \mid \cdots \mid d_n$.

Equivalently,

$$M \cong F \oplus \bigoplus_{i=1}^n R/(p_i^{s_i})$$

where F is free of finite rank, $p_i \in R$ are (not necessarily distinct) prime elements (the *elementary divisors*), and $s_i \in \mathbb{Z}^{\geq 1}$.

2.2.2 Part 2

Since \mathbb{Z}^4 is a finitely generated module over the PID \mathbb{Z} , the structure theorem applies, and we can write $M \cong \mathbb{Z}^k \oplus \bigoplus \mathbb{Z}/(r_i)$ for some $k \leq 4$ and some collection r_i of invariant factors.

If we write $M \cong \mathbb{Z}^4/N$ where N is the submodule generated by the prescribed relations, then we can construct a homomorphism of \mathbb{Z} -modules $L : \mathbb{Z}^4 \rightarrow N$ which is given by the matrix

$$A_L = \begin{pmatrix} 3 & 12 & 3 & 6 \\ 0 & 6 & 0 & 0 \\ -3 & 6 & -3 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

Then $\text{im } A_L \cong N$, and we can compute the Smith normal form,

$$\text{SNF}(A_L) = \begin{pmatrix} 3 & 0 & 0 & 0 \\ 0 & 6 & 0 & 0 \\ 0 & 0 & 6 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

which shows that the invariant factors are 3, 6, 6, 0. We can thus write $\text{im } A_L \cong 3\mathbb{Z} \oplus 6\mathbb{Z} \oplus 6\mathbb{Z}$, and so

$$M \cong \frac{\mathbb{Z}^4}{3\mathbb{Z} \oplus 6\mathbb{Z} \oplus 6\mathbb{Z}} \cong \mathbb{Z} \oplus \mathbb{Z}/(3) \oplus \mathbb{Z}/(6) \oplus \mathbb{Z}/(6).$$

2.3 Problem 10

2.3.1 Part 1

An element $x \in M$ is *torsion* iff there exists some nonzero $r \in R$ such that $rx = 0$, or equivalently $\text{Ann}(x) \neq 0$.

2.3.2 Part 2

Let $R = \mathbb{C}[x]$, $M = \mathbb{C}^2$, and

$$A = \begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix} \in M_2(\mathbb{C}).$$

Then \mathbb{C}^2 is a module over $\mathbb{C}[x]$ with action given by

$$p(x) \curvearrowright \mathbf{v} := p(A)\mathbf{v}$$

Then M is cyclic as an R -module and generated by the basis vector $[1, 0]^T \in \mathbb{C}^2$, since

$$\begin{aligned}
& (tA + s) \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} x \\ y \end{bmatrix} \\
\Rightarrow & \begin{bmatrix} t & 2t \\ 2t & t \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} + \begin{bmatrix} s \\ 0 \end{bmatrix} = \begin{bmatrix} x \\ y \end{bmatrix} \\
& \Rightarrow \begin{bmatrix} t+s \\ 2t \end{bmatrix} = \begin{bmatrix} x \\ y \end{bmatrix} \\
& \Rightarrow \begin{bmatrix} 1 & 1 \\ 2 & 0 \end{bmatrix} \begin{bmatrix} t \\ s \end{bmatrix} = \begin{bmatrix} x \\ y \end{bmatrix}
\end{aligned}$$

which is a linear system of equations represented by an invertible matrix, which always has a solution. So every $\mathbf{v} \in \mathbb{C}^2$ is the image of some polynomial in A .

It is then easy to see that \mathbb{C}^2 is torsion as a module over $\mathbb{C}[x]$, since by Cayley-Hamilton we have $\text{Ann}(A) = (\text{minpoly}(A)) = (x^2 - 2x - 3)$, and so letting $p(x) = x^2 - 2x - 3$, we find that

$$\forall \mathbf{v} \in \mathbb{C}^2 \quad p(A) \curvearrowright \mathbf{v} = 0 \curvearrowright \mathbf{v} = 0.$$

2.3.3 Part 3

Suppose R is a domain, M an R -module, and let

$$T(M) = \{m \in M \mid rm = 0 \text{ for some } r \neq 0 \in R\}.$$

Then $T(R)$ is a submodule iff for all $r \in R$ and all $m, n \in T(M)$ we have $rm + n \in T(M)$.

So pick annihilators $a_m, a_n \neq 0 \in R$ where $a_m m = 0$ and $a_n n = 0$.

Since $a_m \neq 0$ and $a_n \neq 0$, the product $a_m a_n \neq 0$ **because R is a domain**.

Since $0 \in T(M)$, we can suppose $rm + n \neq 0$ (otherwise this is in $T(M)$ trivially). Then

$$\begin{aligned}
a_m a_n (rm + n) &= a_m a_n r m + a_m a_n n \\
&= r a_n (a_m m) + a_m (a_n n) \\
&= r a_n 0 + a_m 0 \\
&= 0.
\end{aligned}$$

where the commutativity of r, a_n, a_m follows from the fact that these are all elements of R , which is a domain, and in particular is commutative. \square
