Summary:

1. Mordell-Weil theorem
 - For elliptic curves over global fields (number fields, function fields, finite fields, etc)
 - Proof uses Galois cohomology and height functions, essentially one proof!
 - Holds for abelian varieties, but more difficult (need an analog of height functions, i.e. an x -coordinate)
2. Height functions (possibly)

3. Elliptic curves over \mathbb{Q}_p or complete discrete valuation fields (see Silverman for basics, possibly Chapter 5), particularly Tate curves
4. Weil-Chatelet groups E/k related to $H^1(k; E)$ with coefficients in the elliptic curve
5. Galois representation of E/k for $\text{char } k = 0$, for $\rho_n g_k \rightarrow \text{GL}(2, \mathbb{Z}/n\mathbb{Z})$ which leads to $\hat{\rho} : g_k \rightarrow \text{GL}(\hat{\mathbb{Z}})$.

2 Mordell-Weil Groups

Let E/k be an elliptic curve over a field k , i.e. a smooth, projective, geometrically integral curve of genus 1 with a k -rational point O .

Note: Silverman good for foundations, but assumes k is perfect! Here we'll assume k is arbitrary.

Remark: If k is not algebraically closed, such a point O may not exist.

By Riemann-Roch (easy computation) E embeds (non-canonically) into \mathbb{P}^2/k as a Weierstrass cubic

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6 \quad \Delta \neq 0.$$

This is a smoothness condition, and this equation has a k -rational point at infinity $[0 : 1 : 0]$. The line at infinity is a flex line (?), and so only intersects this curve at one point.

If $\text{char } k \neq 2, 3$ then $y^2 = x^3 + Ax + B$.

Every elliptic curve is given by a Weierstrass equation, although not in a unique way.

An amazing fact: The k -rational points $E(k)$ forms an abelian group with zero as the identity.

Proof:

1. Given any plane cubic C/k and an origin $O \in C(k)$, the chord and tangent process yields a group structure. Note that there is a symmetry in connecting rational points a, b with a line intersecting at another rational point c which is not present in most groups, so an additional inversion about O is needed to actually make this into a group. Proving associativity: difficult!
2. Look at $\text{Pic}^0 E$, the degree 0 divisors on E mod birational equivalence (?), which is equal to the degree 0 line bundles on E mod bundle isomorphism.

Exercise: Show there is a map $C(k) \rightarrow \text{Pic}^1 C$ given by sending p to its equivalence class; this is a bijection by Riemann-Roch (straightforward exercise).

We can then compose this with a map $\text{Pic}^1 \rightarrow \text{Pic}^0 C$ given by $D \mapsto D - [O]$, which decreases the degree by 1. This gives a map $\Phi : C(k) \rightarrow \text{Pic}^0 C$, just need to check that $\Phi(P \oplus Q) = \Phi(P) + \Phi(Q)$.

Check that the groups are independent of the k -rational point chosen, i.e. changing rational points yields isomorphic groups. So the group law itself does actually depend on the rational point, although the structure doesn't.

Exercise: Let $(E, O)/k$ be an elliptic curve and define $E^0 = E \setminus \{O\}$ the (nonsingular, integral) affine curve given by removing the point at infinity. Then the affine coordinate ring $k[E^0]$ is defined as $k[x, y]/(y^2 - x^3 - Ax - B)$, which is a Dedekind ring.

The interesting thing about Dedekind domains: the ideal class group! (i.e. the Picard group)

This has ideal class group $\text{Pic}[E^0]$, and one can show that

$$\begin{aligned} \text{Pic}^0 E &\longrightarrow \text{Pic}[E^0] \\ \sum_p n_p \deg(p)[p] &\mapsto \sum_{p \neq 0} n_p [p] = \prod_p p^{n_p} \end{aligned}$$

with the sum ranging over all closed points is an isomorphism.

Just note that the RHS can't have a point at infinity, so we just forget it. The isomorphism follows from some exact sequence with correction terms that vanish.

So the Mordell-Weil group of $E(k)$ is isomorphic to $\text{Pic}[E^0]$, the class group of a dedekind domain (?).

Definitions: Let G be a commutative group.

- G is a *class group* iff there exists a dedekind domain R such that $G \cong \text{Pic} R$.
- G is an (*elliptic*) *Mordell-Weil group* iff there exists a field k and an elliptic curve E/k such that $G \cong E(k)$.

Questions:

1. Which G are class groups?
2. Which G are Mordell-Weil groups?

An answer to question 1:

Theorem (Clayborn, 1966): Every commutative G is a class group.

Subsequent proofs: Leatham-Green (1972) and Clark (2008) following Rosen, and uses elliptic curves. See the end of Pete's Commutative Algebra notes!

An answer to question 2:

Consider E/\mathbb{C} , then $E(\mathbb{C}) \cong S^1 \times S^1$, so the torsion subgroup is $T(1) := (\mathbb{Q}/\mathbb{Z})^2 = \bigoplus_{\ell} (\mathbb{Q}_{\ell}/\mathbb{Z}_{\ell})^2$.

This in fact holds for any algebraically closed field of characteristic zero.

Fact: For any E/k , the Mordell-Weil group $E(k)$ is “ $T(1)$ -constrained”, i.e. $E(k)[\text{tors}] \hookrightarrow T(1)$.

Theorem (Clark, 2012): G is a Mordell-Weil group $\iff G$ is $T(1)$ -constrained.

Note: the analogous statement for abelian varieties, i.e being $T(g)$ constrained for some other genus $g \neq 1$, is open. Fixing $k = \mathbb{Q}$ still yields very interesting problems. Computing the rank and torsion subgroups is currently open, and the subject of modern research.

3 Monday January 13th

3.1 Every Abelian Group is a Class Group

Theorem 3.1 (Claborn - Leedham - Green - Clark).

Any commutative group is the class group of some Dedekind domain.

Also see: partial re-proof by Rosen that uses elliptic curves. This theorem: mostly a proof in commutative algebra, see end of Pete's commutative algebra notes.

3.2 Proof Sketch

Let E/k be an elliptic curve over a field.

3.2.1 Step 1

Note that $\text{End}_k(E) \cong_{\mathbb{Z}} \mathbb{Z}^{a(E)}$ where $a(E) \in \{1, 2, 4\}$.

Could be \mathbb{Z} as a \mathbb{Z} -module, could be an order in the imaginary quadratic field (e.g. a quaternion algebra)

There is a short exact sequence

$$0 \longrightarrow E(k) \longrightarrow E(k(E)) \longrightarrow \text{End}_K(E) \longrightarrow 0.$$

This splits because (as seen above), the RHS term is free and thus projective. So

$$E/k(E) \cong E(k) \oplus \mathbb{Z}^{a(E)}.$$

Note that $k(E)$ is an extension of E_k to $E_{k(E)}$ the field of rational functions over k ? (function field). To simplify, take $a(E) = 1$ and $E(k) = \{0\}$.

Taking $k = \mathbb{Q}$, this happens (probably, asymptotically) half of the time. It's easy to write down an elliptic curve that satisfies these conditions

Then $E/k(E) \cong \mathbb{Z}$.

Now pass to the field of rational functions over this field, taking $E(k(E))$. Then $k^2(E) := k(E)(E/k(E))$, and inductively define $k^n(E)$ by passing to function fields. So $E(k^n(E)) \cong \mathbb{Z}^n$.

So we can construct elliptic curves that have any free commutative group as their Mordell-Weil group.

3.2.2 Step 2

Loosely speaking, we'll iterate this process transfinitely. Then for any set S , there exists a field k and an elliptic curve E/k such that $E(k) \cong \bigoplus_S \mathbb{Z}$. We now want to introduce a process that allows passing to quotients. And $R := k[E^0]$ is the affine coordinate ring of E , remove the point at infinity (∞).

3.2.3 Step 3

Let R be a Dedekind domain. Note it has a fraction field with a certain ideal class group. Let $W \subset \text{maxSpec}(R)$, then

$$R^W := \bigcap_{\mathfrak{p} \in \text{maxSpec } R \setminus W} R_{\mathfrak{p}}.$$

Then R^W is Dedekind (and every overring of a Dedekind domain is of this form) and $\max\text{Spec } (R^W) = \max\text{Spec } (R \setminus W)$.

Then

$$\text{Pic } R^W = \text{Pic } R / \langle [\mathfrak{p}] \mid \mathfrak{p} \in W \rangle.$$

Note that if $(A, +)$ is a commutative group, writing $A = \bigoplus_S \mathbb{Z}/H$, we have a Dedekind domain $R = k[E^0]$ such that $\text{Pic } R = \bigoplus_S \mathbb{Z}$.

Note: $\text{Pic } R$ is the class group.

Definition 3.1 (Replete).

A Dedekind domain R is **replete** iff every element of the class group $\text{Pic } R$ is the class group $[\mathfrak{p}]$ of some ideal $\mathfrak{p} \in \max\text{Spec } (R)$.

Is every ideal class the class of a prime ideal? For k a field, $R = \mathbb{Z}_k$. This follows from Chebotom (?) Density (most important theorem for arithmetic geometers!)

Definition 3.2 (Weakly Replete).

A Dedekind domain R is **weakly replete** iff every subgroup $H \subset \text{Pic } R$ is generated by classes of prime ideals.

Exercise (Easy) $K[E^0]$ is weakly replete, and an easy application of Riemann-Roch shows that if $0 \neq p \in E(k) = \text{Pic } k[E^0]$, then $[p] \in \text{Pic } k[E^0]$ is generated by a prime ideal.

Note: most applications of Riemann-Roch to elliptic curves are easy! In this case, it gives you an identification $E \cong \text{Pic } {}^1(E)$.

So there exists a subset $W \subset \max\text{Spec } k[E^0]$ such that $\langle [p] \mid p \in W \rangle = H$. Then

$$\text{Pic } k[E^0]^W \cong \bigoplus_S \mathbb{Z}/H \cong A.$$

■

Note that Dedekind domains don't have to be replete or even weakly replete. The class group of a Dedekind domain could be \mathbb{Z} , and the class of every prime ideal could be $1 \in \mathbb{Z}$

Proof (Claborn).

Start with an arbitrary Dedekind domain R and attach one that's replete.

Can ask for a similar result for abelian varieties, there are conjectures here, few clear results. Need to get $\mathbb{Z}/(m) \times \mathbb{Z}/(n)$, since these occur as Mordell-Weil groups. Take a modular curve and a generic point. Look at universal elliptic curves over elliptic curves and take their Mordell-Weil groups (?)

If k is algebraically closed and $\text{char } k = p$, can't have $\mathbb{Z}(p) \times \mathbb{Z}(p)$. Consider the p -primary torsion $E_k[p^\infty]$. It is zero iff E is supersingular (no points of order p). It is $\mathbb{Q}_p/\mathbb{Z}_p = \varinjlim_n \mathbb{Z}/(p^n)$ iff E is ordinary.

Can sometimes reduce to cases where $k = \mathbb{C}$ and do things analytically. ■

3.3 Mordell-Weil

Theorem 3.2 (Mordell-Weil).

Let k be a global field (extension of \mathbb{Q} or function field over \mathbb{F}_p) and E/k an elliptic curve. Then $E(k) \cong \mathbb{Z}^r \oplus T$ (by classification of abelian groups) where T is finite, and $T \cong \mathbb{Z}/(m) \oplus \mathbb{Z}/(n)$ for $m \mid n$. So T is generated by at most two elements.

Proof (3 steps).

Step 1: Weak Mordell-Weil theorem.

Take any $n \geq 2$ and char k not dividing n . Show that $E(k)/nE(k)$ is finite.

Step 2: Define a height function $h : E(k) \rightarrow \mathbb{R}$ satisfying 3 properties (see next time). This is approximately a quadratic form.

Decompose at places of a number field, see Number Theory II.

Step 3: For any commutative group A , there is a notion of a height function

$$h : A \rightarrow \mathbb{R}.$$

Show the Height Descent Theorem: if A admits a height function and A/nA is finite for some $n \geq 2$, then A is finitely generated.

Also how you'd prove this theorem for abelian varieties, more difficulty defining h . ■
