1 Friday January 10

Recall that \mathbb{C} is a field, where

$$z = x + iy \implies \bar{z} = x - iy$$

and if $z \neq 0$ then

$$z^{-1} = \frac{\bar{z}}{|z|^2}$$

Lemma 1.1 (*Triangle Inequality*).

$$|z + w| \leq |z| + |w|.$$

Proof .

$$(|z| + |w|)^2 - |z + w|^2 = 2(|z\bar{w}| - \Re z\bar{w}) \geq 0.$$

■

Lemma 1.2 (*Reverse Triangle Inequality*).

$$||z| - |w|| \leq |z - w|.$$

Proof .

$$|z| = |z - w + w| \leq |z - w| + |w| \implies |w| - |z| \leq |z - w| = |w - z|.$$

■

Fact $(\mathbb{C}, |\cdot|)$ is a normed space.

Definition 1.2.1 (Limits of Complex Sequences).

$$\lim z_n = z \iff |z_n - z| \longrightarrow 0 \in \mathbb{R}.$$

Definition 1.2.2 (Complex Discs).

A *disc* is defined as $D_r(z_0) := \{z \in \mathbb{C} \mid |z - z_0| < r\}$, and a subset is open iff it contains a disc. By convention, D_r denotes a disc about $z_0 = 0$.

Definition 1.2.3 (Convergence in).

$\sum_k z_k$ *converges* iff $S_N := \sum_{|k| < N} z_k$ converges.

Note that $z_n \longrightarrow z$ and $z_n = x_n + iy_n$, and

$$|z_n - z| = \sqrt{(x_n - x)^2 + (y_n - y)^2} < \varepsilon \implies |x - x_n|, |y - y_n| < \varepsilon.$$

Since \mathbb{R} is complete iff every Cauchy sequence converges iff every bounded monotone sequence has a limit.

Note: This is useful precisely when you don't know the limiting term.

Note that $\sum_k z_k$ thus converges if $\left| \sum_{k=m}^n z_k \right| < \varepsilon$ for m, n large enough, so sums converges iff they have small tails.

Definition 1.2.4 (Absolute Convergence).

$S_N = \sum_{k=1}^N z_k$ converges absolutely iff $\tilde{S} := \sum_{k=1}^{\infty} |z_k|$ converges.

Note that the partial sums $\sum_{k=1}^N |z_k|$ are monotone, so \tilde{S}_N converges iff the partial sums are bounded above.

Definition 1.2.5 (Power Series).

A sum of the form $\sum_{k=0}^{\infty} a_k z_k$ is a *power series*.

Examples:

$$\sum x^k = \frac{1}{1-x}$$

$$\sum (-x^2)^k = \frac{1}{1+x^2}.$$

Note that both of these have a radius of convergence equal to 1, since the first has a pole at $x = 1$ and the second as a pole at $x = i$.

2 Monday January 13th

Recall that $\sum z_k$ converges iff $s_n = \sum_{k=1}^n z_k$ converges.

Lemma 2.1.

Absolute convergence implies convergence.

The most interesting series: $f(z) = \sum a_k z^k$, i.e. power series.

Lemma 2.2 (Divergence).

If $\sum z_k$ converges, then $\lim z_k = 0$.

Corollary 2.3.

If $\sum z_k$ converges, $\{z_k\}$ is uniformly bounded by a constant $C > 0$, i.e. $|z_k| < C$ for all k .

Proposition: If $\sum a_k z_k$ converges at some point z_0 , then it converges for all $|z| < |z_0|$.

Note that this inequality is necessarily strict. For example, $\sum \frac{z^{n-1}}{n}$ converges at $z = -1$ (alternating harmonic series) but not at $z = 1$ (harmonic series).

Proof.

Suppose $\sum a_k z_1^k$ converges. The terms are uniformly bounded, so $|a_k z_1^k| \leq C$ for all k . Then we have

$$|a_k| \leq C/|z_1|^k$$

, so if $|z| < |z_1|$ we have

$$|a_k z^k| \leq |z|^k \frac{C}{|z_1|^k} = C(|z|/|z_1|)^k.$$

So if $|z| < |z_1|$, the parenthesized quantity is less than 1, and the original series is bounded by a geometric series. Letting $r = |z|/|z_1|$, we have

$$\sum |a_k z^k| \leq \sum cr^k = \frac{c}{1-r},$$

and so we have absolute convergence. ■

Exercise (future problem set) Show that $\sum \frac{1}{k} z^{k-1}$ converges for all $|z| = 1$ except for $z = 1$. (Use summation by parts.)

Definition 2.3.1 (Radius of Convergence).

The *radius of convergence* of a series is the real number R such that $f(z) = \sum a_k z^k$ converges precisely for $|z| < R$ and diverges for $|z| > R$.

We denote a disc of radius R centered at zero by D_R . If $R = \infty$, then f is said to be *entire*.

Proposition 2.4.

Suppose that $\sum a_k z^k$ converges for all $|z| < R$. Then $f(z) = \sum a_k z^k$ is continuous on D_R , i.e. using the sequential definition of continuity, $\lim_{z \rightarrow z_0} f(z) = f(z_0)$ for all $z_0 \in D_R$.

Recall that $S_n(z) \rightarrow S(z)$ uniformly on Ω iff $\forall \varepsilon > 0$, there exists a $M \in \mathbb{N}$ such that

$$n > M \implies |S_n(z) - S(z)| < \varepsilon$$

for all $z \in \Omega$

Note that arbitrary limits of continuous functions may not be continuous. Counterexample: $f_n(x) = x^n$ on $[0, 1]$; then $f_n \rightarrow \delta(1)$. This uniformly converges on $[0, 1 - \varepsilon]$ for any $\varepsilon > 0$.

Exercise Show that the uniform limit of continuous functions is continuous.

Hint: Use the triangle inequality.

Proof (of proposition).

Write $f(z) = \sum_{k=0}^N a_k z^k + \sum_{k=N+1}^{\infty} a_k z^k := S_N(z) + R_N(z)$. Note that if $|z| < R$, then there exists a T such that $|z| < T < R$ where $f(z)$ converges uniformly on D_T .

Check!

We need to show that $|R_N(z)|$ is uniformly small for $|z| < s < T$. Note that $\sum a_k z^k$ converges on D_T , so we can find a C such that $|a_k z^k| \leq C$ for all k . Then $|a_k| \leq C/T^k$ for all k , and so

$$\begin{aligned} \left| \sum_{k=N+1}^{\infty} a_k z^k \right| &\leq \sum_{k=N+1}^{\infty} |a_k| |z|^k \\ &\leq \sum_{k=N+1}^{\infty} (C/T^k) s^k \\ &= C \sum_{k=N+1}^{\infty} |s/T|^k \\ &= C \frac{r^{N+1}}{1-r} = C \varepsilon_n \rightarrow 0, \end{aligned}$$

which follows because $0 < r = s/T < 1$.

So $S_N(z) \rightarrow f(z)$ uniformly on $|z| < s$ and $S_N(z)$ are all continuous, so $f(z)$ is continuous. ■

There are two ways to compute the radius of convergence:

- Root test: $\lim_k |a_k|^{1/k} = L \implies R = \frac{1}{L}$.
-
- Ratio test: $\lim_k |a_{k+1}/a_k| = L \implies R = \frac{1}{L}$.

As long as these series converge, we can compute derivatives and integrals term-by-term, and they have the same radius of convergence.

3 Wednesday January 15th

See references: Taylor's Complex Analysis, Stein, Barry Simon (5 volume set), Hormander (technically a PDEs book, but mostly analysis)

Good Paper: Hormander 1955

We'll mostly be working from Simon Vol. 2A, most problems from from Stein's Complex.

3.1 Topology and Algebra of \mathbb{C}

To do analysis, we'll need the following notions:

1. Continuity of a complex-valued function $f : \Omega \rightarrow \mathbb{C}$
2. Complex-differentiability: For $\Omega \subset \mathbb{C}$ open and $z_0 \in \Omega$, there exists $\varepsilon > 0$ such that $D_\varepsilon = \{z \mid |z - z_0| < \varepsilon\} \subset \Omega$, and f is **holomorphic** (complex-differentiable) at z_0 iff

$$\lim_{h \rightarrow 0} \frac{1}{h} (f(z_0 + h) - f(z_0))$$

exists; if so we denote it by $f'(z_0)$.

Example 3.1.

$f(z) = z$ is holomorphic, since $f(z+h) - f(z) = z+h - z = h$, so $f'(z_0) = \frac{h}{h} = 1$ for all z_0 .

Example 3.2.

Given $f(z) = \bar{z}$, we have $f(z+h) - f(z) = \bar{h}$, so the ratio is $\frac{\bar{h}}{h}$ and the limit doesn't exist.

Note that if $h \in \mathbb{R}$, then $\bar{h} = h$ and the ratio is identically 1, while if h is purely imaginary, then $\bar{h} = -h$ and the limit is identically -1 .

We say f is *holomorphic on an open set* Ω iff it is holomorphic at every point, and is holomorphic on a closed set C iff there exists an open $\Omega \supset C$ such that f is holomorphic on Ω .

Fact If f is holomorphic, writing $h = h_1 + ih_2$, then the following two limits exist and are equal:

$$\begin{aligned} \lim_{h_1 \rightarrow 0} \frac{f(x_0 + iy_0 + h_1) - f(x_0 + iy_0)}{h_1} &= \frac{\partial f}{\partial x}(x_0, y_0) \\ \lim_{h_2 \rightarrow 0} \frac{f(x_0 + iy_0 + ih_2) - f(x_0 + iy_0)}{ih_2} &= \frac{1}{i} \frac{\partial f}{\partial y}(x_0, y_0) \\ &\implies \frac{\partial f}{\partial x} = \frac{1}{i} \frac{\partial f}{\partial y}. \end{aligned}$$

So if we write $f(z) = u(x, y) + iv(x, y)$, we have

$$\frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x} \Big|_{(x_0, y_0)} = \frac{1}{i} \left(\frac{\partial u}{\partial y} + i \frac{\partial v}{\partial y} \right) \Big|_{(x_0, y_0)},$$

and equating real and imaginary parts yields **the Cauchy-Riemann equations**:

$$\begin{aligned} \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x} &= -i \frac{\partial u}{\partial y} + \frac{\partial v}{\partial y} \\ \iff \frac{\partial u}{\partial x} &= \frac{\partial v}{\partial y} \quad \text{and} \quad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}. \end{aligned}$$

The usual rules of derivatives apply:

$$1. (\sum f)' = \sum f'$$

Proof.
Direct. ■

$$2. (\prod f)' = \text{product rule}$$

Proof .

Consider $(f(z+h)g(z+h) - f(z)g(z))/h$ and use continuity of g at z . ■

3. Quotient rule

Proof .

Nice trick, write

$$q = \frac{f}{g}$$

so $qg = f$, then $f' = q'g + qg'$ and $q' = \frac{f'}{g} - \frac{fg'}{g^2}$. ■

4. Chain rule

Proof .

Use the fact that if $f'(g(z)) = a$, then

$$f(z+h) - f(z) = ah + r(z, h), \quad |r(z, h)| = o(|h|) \rightarrow 0.$$

Write $b = g'(z)$, then

$$f(g(z+h)) = f(g(z) + bh + r_1) = f(g(z)) + f'(g(z))bh + r_2$$

by considering error terms, and so

$$\frac{1}{h}(f(g(z+h)) - f(g(z))) \rightarrow f'(g(z))g'(z)$$

.

■

4 Friday January 17th

4.1 Antiholomorphic Derivative

Reference: See Lang's Complex Analysis, there are plenty of solution manuals. Note: look for 13 statements equivalent to holomorphic: Springer GTM Lipman.

Let $f; \Omega \rightarrow \mathbb{C}$ be a complex-valued function. Recall that f is *complex differentiable* iff the usual ratio/limit exists. Note that $h = x + iy$ and $h \rightarrow 0 \iff x, y \rightarrow 0$.

We can write

$$f'(z) = \frac{\partial f}{\partial x} = \frac{1}{i} \frac{\partial f}{\partial y}.$$

This follows from Cauchy-Riemann since $u_x = v_y$ and $u_y = -v_x$.

We want to define $\partial, \bar{\partial}$ operators. We have the identities

$$x = \frac{z + \bar{z}}{2} \quad y = \frac{z - \bar{z}}{2i}.$$

We can then write

$$\begin{aligned} dz &= dx + i dy \\ d\bar{z} &= dx - i dy. \end{aligned}$$

We define the dual operators by $\left\langle \frac{\partial}{\partial z}, dz \right\rangle = 1$ and similarly $\left\langle \frac{\partial}{\partial \bar{z}}, d\bar{z} \right\rangle = 1$.

By the chain rule, we can write

$$\begin{aligned} f_z &= \frac{\partial f}{\partial x} \frac{\partial x}{\partial z} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial z} \\ &= \frac{1}{2} \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} \frac{1}{2i} \\ &= \frac{1}{2} \left(\frac{\partial}{\partial x} + i \frac{\partial}{\partial y} \right) f, \end{aligned}$$

and similarly

$$\begin{aligned} f_{\bar{z}} &= \frac{\partial f}{\partial x} \frac{\partial x}{\partial \bar{z}} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial \bar{z}} \\ &= \frac{1}{2} \left(\frac{\partial}{\partial x} - \frac{1}{2i} \frac{\partial}{\partial y} \right) f. \end{aligned}$$

We thus find $\partial_x = \partial_z + \partial_{\bar{z}}$ and $\partial_y = i(\partial_z - \partial_{\bar{z}})$, so define

$$\begin{aligned} \partial f &:= \frac{\partial f}{\partial z} dz \\ \bar{\partial} f &:= \frac{\partial f}{\partial \bar{z}} d\bar{z} \\ \implies df &= \frac{\partial f}{\partial z} dz + \frac{\partial f}{\partial \bar{z}} d\bar{z}. \end{aligned}$$

Definition 4.0.1 (Holomorphic and Antiholomorphic Derivatives).

$$\begin{aligned} \partial f &= \frac{1}{2} \left(\frac{\partial}{\partial x} + i \frac{\partial}{\partial y} \right) f \\ \bar{\partial} f &= \left(\frac{\partial}{\partial x} - \frac{1}{2i} \frac{\partial}{\partial y} \right) f. \end{aligned}$$

Proposition 4.1 (*Holomorphic Functions have vanishing antiholomorphic derivatives*).

f is holomorphic iff $\bar{\partial}f = 0$.

This means that f depends on z alone and not \bar{z} .

Proof.

$\bar{\partial}f = 0$ iff $\frac{1}{2}(f_x + if_y) = 0$, so $(u_x - v_y) + i(v_x + u_y) = 0$.

■

Application to PDEs: we can write

$$u_{xx} = v_{xy} \quad u_{yy} = v_{yx}$$

and so

$$u_{xx} + u_{yy} = 0 = v_{xx} + v_{yy}.$$

Thus $\Delta f = 0$, so f satisfies Laplace's equation and is said to be *harmonic*.

Corollary 4.2 (*Holomorphic Functions Have Harmonic Components*).

If f is analytic, then u, v are both harmonic functions.

Theorem 4.3 (*Chain Rule*).

Let $w = f(z)$ and $g(w) = g(f(z))$. Then

$$h_z = g_w f_z + g_{\bar{w}} \bar{f}_z$$

$$h_{\bar{z}} = g_w f_{\bar{z}} + g_{\bar{w}} \bar{f}_{\bar{z}}.$$

If f, g are holomorphic, $f_{\bar{z}} = g_{\bar{w}} = 0$, so $h_{\bar{z}} = 0$ and h is holomorphic and

$$h_z = g_w f_z.$$

Example 4.1.

Given a power series $f = \sum a_n(z - z_0)^n$. Then

1. There exists a radius of convergence R such that f converges precisely on $D_R(z_0)$.
2. f is continuous on $D_R(z_0)^\circ$.
3. By the root test, $R = (\limsup |a_n|^{1/n})^{-1} = \liminf |a_n/a_{n+1}| = (\limsup |a_{k+1}/a_k|)^{-1}$.

Recall the **ratio test**:

$$\sum |a_k| < \infty \iff \limsup |a_{k+1}/a_k| < 1$$

Theorem 4.4 (*Holomorphic series can be differentiated term-by-term*).

If $f(z) = \sum_{n=0}^{\infty} a_n z^n$ is holomorphic on $|z| < R$ for $R > 0$ then

$$f'(z) = \sum_{n=1}^{\infty} a_n n z^{n-1}.$$

Proof.

Given $|z| < R$, fix $r > 0$ such that $|z| < r < R$. Suppose that $|w - z| < r - |z|$, so $|w| < r$.

We want to show

$$|S| = \left| \frac{f(w) - f(z)}{w - z} - \sum_{n=1}^{\infty} a_n n z^{n-1} \right| \rightarrow 0 \quad \text{as } w \rightarrow z.$$

Idea: write everything in terms of power series. Use the fact that $a^n - b^n = (a - b)(a^{n-1} + a^{n-2}b + \dots)$, and so $|(w^k - z^k)/(w - z)| \leq kr^{k-1}$.

$$\begin{aligned}
S &= \sum_{n=1} a_n \left(\frac{w^n - z^n}{w - z} - nz^{n-1} \right) \\
&= \sum_{n=1} a_n (w^{n-1} + w^{n-2}z + \cdots + z^{n-1} + nz^{n-1}) \\
&= \sum_{n=1} a_n ((w^{n-1} - z^{n-1}) + (w^{n-2} - z^{n-2})z + \cdots + (w - z)z^{n-2}) = \sum_{n=1} a_n (w - z)(\cdots + z^{n-2}) \\
&\leq \sum_{n=2} |a_n| \frac{1}{2} n(n-1) r^{n-2} |z - w|.
\end{aligned}$$

■

Exercise Show $\lim_n n^{\frac{1}{n}} = 1$.

Also tricky: show $\lim \sin(n)$ doesn't exist, and $\sin(n)$ is dense in $[-1, 1]$.

Proof.

Consider $\limsup |a_n n|^{\frac{1}{n}}$.

■

Note that an analytic function is holomorphic in its domain of convergence, so analytic implies holomorphic. The converse requires Cauchy's integral formula.

Next time: trying to prove holomorphic functions are analytic.

5 Wednesday January 22nd

5.1 Parameterized Curves

Note: multiple complex variables, see Hormander or Steven Krantz

Recall from last time that if

$$f(z) = \sum_{n=0}^{\infty} a_n z^n$$

with $z_0 \neq 0$ has radius of convergence

$$R = (\limsup |a_n|^{1/n})^{-1} > 0$$

then f' exists and is obtained by differentiating term-by-term.

We know that f analytic $\implies f$ holomorphic (and smooth), and we want to show the converse. For this, we need integration.

Definition 5.0.1 (Parameterized Curves).

A *parameterized curve* is a function $z(t)$ which maps a closed interval $[a, b] \subset \mathbb{R}$ to \mathbb{C} .

Definition 5.0.2 (Smooth Curves).

The curve is said to be *smooth* iff z' exists and is continuous on $[a, b]$, and $z'(t) \neq 0$ for any t . At the boundary $\{a, b\}$, we define the derivative by taking one-sided limits.

Definition 5.0.3 (Piecewise Smooth Curves).

A curve is said to be *piecewise smooth* iff $z(t)$ is continuous on $[a, b]$ and there are $a < a_1 < \dots < a_n = b$ with z smooth on each $[a_k, a_{k+1}]$.

Note that such a curve may fail to have tangent lines at a_i .

Definition 5.0.4 (Equivalent Parameterizations).

Two parameterizations $z : [a, b] \rightarrow \mathbb{C}$, $\tilde{z} : [c, d] \rightarrow \mathbb{C}$ are *equivalent* iff there exists a C^1 bijection $s : [c, d] \rightarrow [a, b]$ where $s \mapsto t(s)$ such that $s' > 0$ and $\tilde{z}(s) = z(s(t))$.

Note that $s' > 0$ preserves orientation and $s' < 0$ reverses orientation.

Definition 5.0.5 (Orientations of Curves).

A curve in *reverse orientation* is defined by

$$\gamma : [a, b] \rightarrow \mathbb{C} \implies \gamma^- : [a, b] \rightarrow \mathbb{C} \\ t \mapsto \gamma(a + b - t).$$

Definition 5.0.6 (Closed Curves).

A curve is *closed* iff $z(a) = z(b)$, and is *simple* iff $z(t) \neq z_{t_1}$ for $t \neq t_1$.

Definition 5.0.7 (Positively Oriented Curves).

For $C_r(z_0) := \{z \mid |z - z_0| = r\}$, the *positive orientation* is given by $z(t) = z_0 + re^{2\pi it}$ for $t \in [0, 1]$.

5.2 Definition of the Integral

Definition 5.0.8 (The Complex Integral).

The *integral* of f over γ is defined as

$$\int_{\gamma} f \, dz = \int_a^b f(z(t)) z'(t) \, dt.$$

Note: this doesn't depend on parameterization, since if $t = t(s)$, then a change of variables yields

$$\int_{\gamma} f \, dz = \int_c^d f(z(t(s))) z'(t(s)) t'(s) \, ds = \int_c^d f(\tilde{z}(s)) \tilde{z}'(s) \, ds.$$

Definition 5.0.9 (Length of a Curve).

The *length* of γ is defined as $|\gamma| = \int |z'(t)| \, dt$.

Proposition 5.1. 1. We can extend this definition to piecewise smooth curves by

$$\int_{\gamma} f \, dz = \sum \int_{a_k}^{a_{k+1}} f \, dz$$

2. This integral is linear and $\int_{\gamma} f = -\int_{\gamma^{-}} f$.
 3. We have an inequality

$$\left| \int_{\gamma} f \right| \leq \max_{a \leq t \leq b} |f(z(t))| |\gamma|.$$

Definition 5.1.1 (Primitive of a Function).

A function F is a *primitive* for f on Ω iff F is holomorphic on Ω and $F'(z) = f(z)$ on Ω .

Recall that in \mathbb{R} , we have

$$F(x) = \int_a^x f(t) \, dt$$

as an antiderivative with $F'(x) = f(x)$, and $\int_a^b f = F(b) - F(a)$.

Theorem 5.2 (*Evaluating Integrals with Primitives*).

If f is continuous, has a primitive F in Ω , and γ is a curve beginning at w_0 and ending at w_1 , then $\int_{\gamma} f = F(w_1) - F(w_0)$.

Proof.

Use definitions, write $z(t)$ where $z(a) = w_1, z(b) = w_2$. Then

$$\begin{aligned} \int_{\gamma} f &= \int_a^b f(z(t)) z'(t) \, dt \\ &= \int_a^b F'(z(t)) z'(t) \, dt \\ &= \int_a^b F_t \, dt \\ &= F(z(b)) - F(z(a)) \quad \text{by FTC} \\ &= F(w_1) - F(w_2). \end{aligned}$$

Note that if γ is piecewise smooth, the sum of the integrals telescopes to yield the same conclusion. ■

Corollary 5.3 (*Functions with Primitives Integrate to Zero Along Loops*).

If f is continuous and γ is a closed curve in Ω , and f has a primitive in Ω , then

$$\oint f = 0.$$

6 Friday January 24th

Corollary 6.1.

If γ is a closed curve on Ω an open set and f is continuous with a primitive in Ω (i.e. an F holomorphic in Ω with $F' = f$) then $\int_{\gamma} f \, dz = 0$.

Proof (easy).

$$\int_{\gamma} f \, dz = \int_{\gamma} F' = F'(z)z(t) \, dt = F(z(b)) - F(z(a)) = 0.$$

■

Corollary 6.2.

If f is holomorphic with $f' = 0$ on Ω , then f is constant.

Proof (easy).

Pick $w_0 \in \Omega$; we want to fix $w_0 \in \Omega$ and show $f(w) = f(w_0)$ for all $w \in \Omega$.

Take any path $\gamma : w_0 \rightarrow w$, then

$$0 = \int_{\gamma} f' = f(w) - f(w_0).$$

■

6.1 Integral and Fourier Transform of e^{-x^2}

Example 6.1.

Let $f(z) = e^{-z^2}$, this is holomorphic. Write

$$f(z) = \sum \frac{(-1)^n z^{2n}}{n!},$$

so

$$\int f = \sum \frac{(-1)^n z^{2n+1}}{n!(2n+1)}.$$

Since f is entire, $\int f$ is entire, and $(\int f)' = f$ so this function has a primitive. Thus

$\int_{\gamma} f(z) = 0$ for any closed curve. So take γ a rectangle with vertices $\pm a, \pm a + ib$.

So

$$\int_{\gamma} f = \int_{-a}^a e^{-x^2} dx + \int e^{-(a+iy)^2} i dy - \int_{-a}^a e^{-(x+ib)^2} dx - \int_0^b e^{-(a+iy)^2} i dy = 0.$$

We can do some estimates,

$$\begin{aligned} e^{-(a+iy)^2} &= e^{-(a^2+2iaiy-y^2)} \\ &= e^{-a^2+y^2} e^{2iaiy} \\ &\leq e^{-a^2+y^2} \\ &\leq e^{-a^2+b^2}, \end{aligned}$$

$$\left| \int_0^b e^{-(a+iy)^2} i dy \right| \leq e^{-a^2+b^2} \cdot b$$

$$\int_{-a}^a e^{-(x^2+2ibx)-b^2} = e^{b^2} \int_{-a}^a e^{-x^2} (\cos(2bx) - i \sin(2bx))$$

$$\stackrel{\text{odd fn}}{=} e^{b^2} \int_{-a}^a e^{-x^2} \cos(2bx) dx.$$

Now take $a \rightarrow \infty$ to obtain

$$\int_{\mathbb{R}} e^{-x^2} dx = e^{b^2} \int_{\mathbb{R}} e^{-x^2} \cos(2bx) dx.$$

We can compute

$$\int_{\mathbb{R}} e^{-x^2} = \left[\left(\int_{\mathbb{R}} e^{-x^2} \right)^2 \right]^{1/2} = \left(\int_0^{2\pi} \int_0^\infty e^{-r^2} r dr d\theta \right) = \sqrt{\pi}.$$

and then conclude

$$\int_{\mathbb{R}} e^{-x^2} \cos(2bx) = \sqrt{\pi} e^{-b^2}.$$

Make a change of variables $2b = 2\pi\xi$, so $b = \pi\xi$, then

$$\int_{\mathbb{R}} e^{-x^2} \cos(2\pi\xi x) dx = \sqrt{\pi} e^{-\pi^2\xi^2}.$$

Thus $\mathcal{F}(e^{-x^2}) = \sqrt{\pi} e^{-\pi^2\xi^2}$, allowing computation of the Fourier transform. Note that this can be used to prove the Fourier inversion formula.

Exercise Show that this is an approximate identity and prove the Fourier inversion formula.

Exercise Show $\mathcal{F}(e^{-ax^2}) = \sqrt{\pi/a} e^{-\pi^2/a\xi^2}$, and thus taking $a = \pi$ makes $e^{\pi x^2}$ is an eigenfunction of \mathcal{F} with eigenvalue 1.

Theorem 6.3 (Holomorphic Integrals Vanish).

If f has a primitive on Ω then $F(z)$ is holomorphic and $\int_{\gamma} f = 0$. If f is holomorphic, then

$$\int_{\gamma} f = 0.$$

Theorem 6.4 (Green's).

Take $\Omega \in \mathbb{R}^2$ bounded with $\partial\Omega$ piecewise smooth. If $f, g \in C^1\bar{\Omega}$, then

$$\int_{\partial\Omega} f dx + g dy = \iint_{\Omega} (g_x - f_y) dA.$$

Proof.
Omitted. ■

Proof (that holomorphic integrals vanish).

Write $\gamma = \partial\Gamma$, and noting that $f_z = f_x = \frac{1}{i}f_y$ implies that $\frac{\partial f}{\partial \bar{z}}$, so

$$\begin{aligned}\int_{\gamma} f \, dz &= \int_{\gamma} f(z) (dx + i dy) \\ &= \int f(z) \, dx + i \int f(z) \, dy \\ &= \iint_{\Gamma} (if_x - f_y) \, dA \\ &= i \iint_{\Gamma} \left(f_x - \frac{1}{i} f_y \right) \, dA \\ &= i \iint_{\Gamma} 0 \, dA \\ &= 0.\end{aligned}$$

■

Next up, we'll prove that this integral over any triangle is zero by a limiting process.

7 Monday January 27th

Open question: does a PDE involving analytic functions always have solutions? Or does this hold with analytic replaced by smooth?

7.1 Green's Theorem

Fix a connected domain Ω which is bounded with a piecewise C^1 boundary.

Theorem 7.1 (Green's).

Given $f, g \in C^1(\bar{\Omega})$, we can take a vector field $F = \langle f, g \rangle$ and have

$$\begin{aligned}\int_{\partial\Omega} f \, dx + g \, dy &= \iint_{\Omega} \left(\frac{\partial g}{\partial x} - \frac{\partial f}{\partial y} \right) \, dA \\ \int_{\partial\Omega} -f \, dx + g \, dy &= \iint_{\Omega} \left(\frac{\partial g}{\partial x} + \frac{\partial f}{\partial y} \right) \, dA \\ \int_{\partial\Omega} f \, dy - g \, dx &= \iint_{\Omega} \left(\frac{\partial f}{\partial x} + \frac{\partial g}{\partial y} \right) \, dA \\ \int_{\partial\Omega} F \cdot \mathbf{n} \, ds &= \iint_{\Omega} \nabla \cdot F \, dA \\ \int_{\partial\Omega} \text{curl}(F) \, ds &= \iint_{\Omega} \text{div}(F) \, dA,\end{aligned}$$

where we take \mathbf{n} to be orthogonal to $\partial\Omega$. The quantities appearing on the RHS are referred to as the flux.

For $f(z) \in C^1(\Omega)$ holomorphic, we can then write

$$\begin{aligned}
\int_{\partial\Omega} f \, dz &= \int_{\partial\Omega} f (dx + idy) \\
&= \int_{\partial\Omega} f \, dx + if \, dy \\
&= \iint_{\Omega} (if_x - f_y) \, dA \\
&= 0,
\end{aligned}$$

which follows since f holomorphic, we can write

$$f'(z) = f_x = \frac{1}{i} f_y,$$

so $if_x = f_y$ and thus $\frac{\partial f}{\partial \bar{z}} = 0$.

See Taylor's Introduction to Complex Analysis

Theorem 7.2 (Cauchy's Integral Formula):

If $f \in C^1(\bar{\Omega})$ and f is holomorphic, then for any $z \in \Omega$

$$f(z) = \frac{1}{2\pi i} \int_{\partial\Omega} \frac{d(\xi)}{\xi - z} \, d\xi.$$

Proof .

Since $z \in \Omega$ an open set, we can find some $r > 0$ such that $D_r(z) \subset \Omega$. Then $\frac{f(\xi)}{\xi - z}$ is holomorphic on $\Omega \setminus D_r(z)$. Let $C_r = \partial D_r(z)$.

Claim:

$$\int_{\partial\Omega} \frac{f(\xi)}{\xi - z} \, d\xi = \int_{C_r} \frac{f(\xi)}{\xi - z} \, d\xi.$$

If we can differentiate through the integral, we can obtain

$$\frac{\partial}{\partial z} f(z) = \frac{1}{2\pi i} \int_{\partial\Omega} \frac{f(\xi)}{(\xi - z)^2} \, d\xi.$$

and thus inductively

$$(D_z)^n f(z) = \frac{n!}{2\pi i} \int_{\partial\Omega} \frac{f(\xi) \, d\xi}{(\xi - z)^{n+1}}.$$

To prove rigorously, need to write

$$\begin{aligned}
\Delta_h f(z) &= \frac{1}{h} (f(z+h) - f(z)) \\
&= \frac{1}{2\pi i h} \int_{\partial\Omega} f(\xi) \left(\frac{1}{\xi - (z+h)} - \frac{1}{\xi - z} \right) \, d\xi = \frac{1}{2\pi i h} \int_{\partial\Omega} f(\xi) \left(\frac{1}{(\xi - z - h)(\xi - z)} \right) \, d\xi,
\end{aligned}$$

and show the integrand converges uniformly, where

$$\frac{1}{(\xi - z - h)(\xi - z)} \xrightarrow{u} \frac{1}{(\xi - z)^2}.$$

Continuing inductively yields the integral formula. ■

Proof (of claim used in main proof).

Use the parameterization of C_r given by $\xi = z + re^{i\theta}$. Then

$$\begin{aligned} \frac{1}{2\pi i} \int_{C_r} \frac{f(\xi)}{\xi - z} d\xi &= \frac{1}{2\pi i} \int_0^{2\pi} \frac{f(z + re^{i\theta})}{re^{i\theta}} i r d\theta \\ &= \frac{1}{2\pi} \int_0^{2\pi} f(z + re^{i\theta}) d\theta \\ &\xrightarrow{r \rightarrow 0} \frac{1}{2\pi} \int_{\partial\Omega} \frac{f(\xi)}{\xi - z}. \end{aligned}$$

where we use the fact that

$$f(z + re^{i\theta}) = f(z) + f'(z)re^{i\theta} + o(r) \xrightarrow{r \rightarrow 0} f(z)$$

Letting

$$F(\xi) = \frac{f(\xi)}{\xi - z},$$

this is holomorphic on $\Omega \setminus D_r(z)$. Let $\Omega_r = \partial\Omega \cup (-C_r)$. Take the following path integral:

Then

$$0 = \int_{\partial\Omega_r} F(\xi) d\xi = \int_{\partial\Omega} F(\xi) d\xi - \int_{C_r} F(\xi) d\xi,$$

which forces these integrals to be equal. ■

Corollary 7.3 (*implies smooth*).

If f is holomorphic, then $f \in C^1(\Omega)$ implies that $f \in C^\infty(\Omega)$.

Theorem 7.4 (*Holomorphic implies analytic*).

If f is holomorphic in Ω , then f is equal to its Taylor series (i.e. $f(z_0)$ is analytic.)

Proof.

Fix $z_0 \in \Omega$ and let $r = |z - z_0|$.

$$\begin{aligned} \frac{1}{\xi - z} &= \frac{1}{\xi - z_0 - (z - z_0)} \\ &= \frac{1}{\xi - z_0} \frac{1}{1 - \left(\frac{z - z_0}{\xi - z_0}\right)} \\ &= \frac{1}{\xi - z_0} \sum_n \left(\frac{z - z_0}{\xi - z_0}\right)^n \quad \text{for } |z - z_0| < |\xi - z_0|. \end{aligned}$$

Note that $\sum z^n$ converges uniformly for any $|z| < \delta < 1$.

Thus

$$\begin{aligned} f(z) &= \frac{1}{2\pi i} \int_{\xi \in \partial\Omega} f(\xi) \sum \frac{(z - z_0)^n}{(\xi - z_0)^{n+1}} d\xi \\ &= \sum \left(\frac{1}{2\pi i} \int \frac{f(\xi)}{(\xi - z_0)^{n+1}} d\xi \right) (z - z_0)^n \\ &= \sum \frac{f^{(n)}(z_0)}{n!} (z - z_0)^n. \end{aligned}$$
■

Corollary 7.5.

f is holomorphic iff f is analytic.

Counterexample to keep in mind:

$$f(x) = \begin{cases} x^2 & x > 0 \\ 0 & x \leq 0 \end{cases}.$$

In the case of \mathbb{R} , smooth and analytic are very different categories of functions.

8 Wednesday January 29th

8.1 Cauchy's Integral Formula

Theorem 8.1 (Cauchy's Integral Formula).

Let $f : \Omega \rightarrow \mathbb{C}$ be holomorphic, so $f \in C^1(\overline{\Omega})$. Then for any $z \in \Omega$,

$$f(z) = \frac{1}{2\pi i} \int_{\partial\Omega} \frac{f(\xi)}{\xi - z} d\xi.$$

In general,

$$f^{(n)}(z) = \frac{n!}{2\pi i} \int_{\partial\Omega} \frac{f(\xi)}{(\xi - z)^{n+1}} d\xi.$$

This implies that f is analytic, i.e.

$$f(z) = \sum a_n(z - z_0)^n \quad \text{where} \quad a_n = \frac{f^{(n)}(z_0)}{n!}.$$

Thus f is holomorphic iff f is analytic,

and

$$\int_{\partial\Omega} f = 0 \implies \int_{\partial\Omega_r} \frac{f(\xi)}{\xi - z} d\xi = 0.$$

where $\Omega_r = \Omega \setminus D_r(z)$, and $\partial\Omega_r = \partial\Omega \cup (-\partial D_r)$.

We can thus shrink integrals:

$$\int_{\partial\Omega} \frac{f(\xi)}{\xi - z} d\xi = \int_{C_r} \frac{f(\xi)}{\xi - z} d\xi.$$

Proposition 8.2 (Homotopy Invariance).

Let $f \in C^1(\Omega)$ be holomorphic on Ω . Let $\gamma_s(t)$ be a family of smooth curves in Ω ; then $\int_{\gamma_s} f$ is independent of s .

Proof.

Write

$$\gamma_s(t) = \gamma(s, t) : [a, b] \times [0, 1] \rightarrow \Omega.$$

We have $\gamma_s(0) = \gamma_s(1)$ so $\frac{\partial \gamma}{\partial s}(s, 0) = \frac{\partial \gamma}{\partial s}(s, 1)$. Then

$$\begin{aligned}
\frac{\partial \gamma}{\partial s} &= \int_0^1 \left(f'(r(s, t)) \frac{\partial r}{\partial s} \frac{\partial r}{\partial t} + f(r(s, t)) \frac{\partial^2 \gamma}{\partial s \partial t} \right) dt \\
&= \int_0^1 \left(f'(r(s, t)) \frac{\partial r}{\partial s} \frac{\partial r}{\partial t} + f(r(s, t)) \frac{\partial^2 \gamma}{\partial t \partial s} \right) dt \\
&= \int_0^1 \frac{\partial}{\partial t} (f(\gamma(s, t)) \gamma_s) \\
&= f(\gamma(s, 1)) \gamma_s(s, 1) - f(\gamma(s, 0)) \gamma_s(s, 0) \\
&= 0.
\end{aligned}$$

where we can just take the paths $\gamma(s, t) = z_0 \in \Omega$ for all s, t . ■

Proposition 8.3 (Pointwise Limit of Locally Uniform is Locally Uniform).

Let $\Omega \subset \mathbb{C}$ be open and $f_v : \Omega \rightarrow \mathbb{C}$. Suppose that each f_v is holomorphic, $f_v \rightarrow f$ pointwise, and *locally uniform*, i.e. $f_v \rightarrow f$ uniformly on every compact $K \subset \Omega$. Then f is holomorphic in Ω and f is locally uniform.

Proof.

Given a compact set $K \subset \Omega$, pick an O with smooth boundary such that $K \subset O \subset \bar{O} \subset \Omega$. We have

$$\begin{aligned}
f_v(z) &= \frac{1}{2\pi i} \int_{\partial O} \frac{f_v(\xi)}{\xi - z} d\xi \\
f_v^{(n)}(z) &= \frac{n!}{2\pi i} \int_{\partial O} \frac{f_v(\xi)}{(\xi - z)^{n+1}} d\xi
\end{aligned}$$

Then on ∂O , we have uniform convergence

$$\frac{f_v(\xi)}{(\xi - z)^{n+1}} \xrightarrow{u} \frac{f(\xi)}{(\xi - z)^{n+1}}.$$

By moving the limits inside, we obtain

$$\begin{aligned}
f(z) &= \frac{1}{2\pi i} \int_{\partial O} \frac{f(\xi)}{\xi - z} d\xi \\
f^{(n)}(z) &= \frac{n!}{2\pi i} \int_{\partial O} \frac{f(\xi)}{(\xi - z)^{n+1}} d\xi
\end{aligned}$$

■

Theorem 8.4 (Cauchy's Inequality).

Given $z_0 \in \Omega$, pick the largest disc $D_R(z_0) \subset \Omega$ and let $C_R = \partial D_R$. Using the integral formula, defining $\|f\|_{C_R} = \max_{|z-z_0|=R} |f(z)|$

$$|f^{(n)}(z_0)| \leq \frac{n!}{2\pi} \int_0^{2\pi} \frac{\|f\|_{C_R}}{R^{n+1}} R d\theta = \frac{n! \|f\|_{C_R}}{R^n}.$$

Corollary 8.5 (Liouville's Theorem).

If f is entire and bounded, then f is constant.

Proof.

For all $z_0 \in \mathbb{C}$, there exists an M such that $|f(z)| \leq M$. Then $|f'(z_0)| \leq \frac{M}{R}$ for any $R > 0$. Taking $R \rightarrow \infty$ yields $f'(z_0) = 0$, so f is constant. ■

Corollary 8.6 (Weak Fundamental Theorem of Algebra).

Every non-constant polynomial $p(z) = a_0 + a_1 z + \cdots + a_n z^n$ has a root in \mathbb{C} .

Remark: A general proof technique is when proving something for $f(z)$, consider $\frac{1}{f(z)}$ and $f(\frac{1}{z})$.

Proof.

Suppose p is nonconstant and does not have a root, $\frac{1}{p}$ is entire. Assume that $a_n \neq 0$, then

$$\frac{p(z)}{z^n} = a_n \left(\frac{a_{n-1}}{z} + \cdots + \frac{a_0}{z^n} \right) := a_n + y$$

We can note that $\lim_{z \rightarrow \infty} \frac{a_{n-k}}{z^k} \rightarrow 0$, so there exists an $R > 0$ such that

$$\begin{aligned} \left| \frac{p(z)}{z^n} \right| &\geq \frac{1}{2} |a_n| \quad \text{for } |z| > R \\ \implies |p(z)| &\geq \frac{1}{2} |a_n| |z|^n \geq \frac{1}{2} |a_n| R^n. \end{aligned}$$

Since $p(z)$ is continuous and has no root in the disc $|z| \leq R$, $|p(z)|$ is bounded from below in this disc. Since $p(z)$ is continuous on a compact set, it attains a minimum, and so $|p(z)| \geq \min_{|z| \leq R} |p(z)| = c_2 \neq 0$. Then $|p(z)| \geq A = \min(c_2, \frac{1}{2} |a_n| R^n)$, so $\frac{1}{p}$ is bounded. Then f is constant, a contradiction. ■

9 Friday January 31st

9.1 Fundamental Theorem of Algebra

Recall that if f is holomorphic, we have Cauchy's integral formula.

Corollary 9.1 (Weak Fundamental Theorem of Algebra).

If $P(z)$ is a polynomial in \mathbb{C} then P has a root in \mathbb{C} .

Proof.

See previous notes. ■

Corollary 9.2 (Fundamental Theorem of Algebra).

Every polynomial of degree n has precisely n roots in \mathbb{C} .

Proof.

By induction on the degree of P . From the first corollary, P has a root w_1 , so write $z = z - w_1 + w_1$. Then

$$\begin{aligned} p(z) &= p(z - w_1 + w_1) \\ &= \sum_k^n a_k (z - w_1 + w_1)^k \\ &= \sum_k^n a_k \sum_j^k \binom{k}{j} w_1^{k-j} (z - w_1)^j \\ &= \sum_k^n \sum_j^k a_k \binom{k}{j} w_1^{k-j} (z - w_1)^j \\ &= \sum_j^n \left(\sum_{k \geq j} a_k \binom{k}{j} \right) (z - w_1)^j \\ &= b_0 + b_1(z - w_1) + \cdots + b_n(z - w_1)^n. \end{aligned}$$

Since $P(w_1) = 0$, we must have $b_0 = 0$, and thus this equals

$$\begin{aligned} b_1(z - w_1) + \cdots + b_n(z - w_1)^n &= (z - w_1)(b_1 + \cdots + b_n(z - w_1)^{n-1}) \\ &:= (z - w_1)\phi(z), \end{aligned}$$

where $\phi(z)$ is degree $n - 1$, which has $n - 1$ roots by induction. ■

Definition 9.2.1 (Characterizations of Limit Points).

For a sequence $\{z_n\}$, TFAE

1. z is a limit point.

2. There exists a subsequence $\{z_{n_k}\}$ converging to z .
3. For every $\varepsilon > 0$, there are infinitely many z_i in $D_\varepsilon(z)$.

Theorem 9.3 (*Only the zero function vanishes on a sequence in a domain (Stein 4.8)*).

Suppose f is holomorphic on a bounded connected region Ω and f vanishes on a sequence of distinct points with a limit point in Ω . Then f is identically zero.

Proof.

WLOG by restricting to a subsequence, suppose that $\{w_k\} \in \Omega$ with $f(w_k) = 0$ for all k and z_0 is a limit point of $\{w_k\}$. Let $U = \{z \in \Omega \mid f(z) = 0\}$. Then

1. U is nonempty since $f(w_k) = f(z_0) = 0$.
2. Since holomorphic functions are continuous, if $w_k \rightarrow z$ then $z \in U$, so U is closed.
3. (To prove) U is open.

Since U is closed and open, $U = \Omega$.

We will first show that $f(z) \equiv 0$ in a disk containing z_0 . Choose a disc D containing z_0 and contained in Ω . Since f is holomorphic on D , we can write

$$f(z) = \sum a_n (z - z_0)^n.$$

Since $f(z_0) = 0$, we have $a_0 = 0$.

Suppose $f \not\equiv 0$. Then there exists a smallest $n \in \mathbb{Z}^+$ such that $a_n \neq 0$, so $f(z) = a_n (z - z_0)^n + \dots$. Since $a_n \neq 0$, we can factor this as $a_n (z - z_0)^n (1 + g(z - z_0))$ where

$$g(z - z_0) = \sum_{k=n+1}^{\infty} \frac{a_k}{a_n} (z - z_0)^{k-n}.$$

Note that g is holomorphic, and $g(z_0 - z_0) = 0$.

Choose some w_k such that $f(w_k) = 0$ and $|g(w_k - z_0)| \leq \frac{1}{2}$ by continuity of g . Then

$$|1 + g(w_k - z_0)| > 1 - \frac{1}{2} = \frac{1}{2}.$$

So

$$|f(w_k)| = |a_n (w_k - z_0)^n (1 + g(w_k - z_0))| > |a_n| |w_k - z_0|^n \frac{1}{2} > 0,$$

a contradiction. So U is open, closed, and nonempty, so $U = \Omega$. ■

Corollary 9.4.

Suppose f, g are holomorphic in a region Ω with $f(z_k) = g(z_k)$ where $\{z_k\}$ has a limit point. Then $f(z) \equiv g(z)$.

Theorem 9.5 (*Mean Value*).

Let z_0 be a point in Ω and C_γ the boundary of $D_\gamma(z_0)$. Then

$$\begin{aligned}
f(z_0) &= \frac{1}{2\pi i} \int_{C_\gamma} f(z)/(z - z_0) dz \\
&= \frac{1}{2\pi i} \int_0^{2\pi} f(z_0 + re^{i\theta})/re^{i\theta} rie^{i\theta} d\theta \quad \text{by } z = z_0 + re^{i\theta} \\
&= \frac{1}{2\pi} \int_0^{2\pi} f(z_0 + re^{i\theta}) d\theta \\
&= \frac{1}{2\pi r} \int_0^{2\pi} f(z_0 + re^{i\theta}) r d\theta \\
&= \frac{1}{|C_\gamma|} \int_0^{2\pi} f(z) ds,
\end{aligned}$$

which is the average value of f on the circle.

Note that there is another formula that averages over the disc (see book for derivation?)

$$f(z_0) = \frac{1}{D_s(z_0)} \int_{P_s} \int_{D_s} f(z) dA.$$

These imply the maximum modulus principle, since the average can not be the max or min unless f is constant. Note that $|f(z)|$ is continuous!

Next time: maximum modulus principle.

10 Monday February 3rd

10.1 Mean Value Theorem

Theorem 10.1 (Mean Value for Holomorphic functions).

$$f(z_0) = \frac{1}{\pi r^2} \iint_{D_r(z_0)} f(z) dA$$

Proof (of MVT?).

Let $f : \Omega \rightarrow \mathbb{C}$ be holomorphic where Ω is open and connected. Then by Cauchy's integral formula, we have $f(z_0) = \frac{1}{2\pi} \int_0^{2\pi} f(z_0 + re^{i\theta}) d\theta$ for any $z_0 \in \Omega$.

We can consider $D_r(z_0)$, in which case we have for all $0 < s < r$,

■

$$\begin{aligned}
f(z_0) &= \frac{1}{2\pi} \int_0^{2\pi} f(z_0 + se^{i\theta}) d\theta \\
\implies s \cdot f(z_0) &= \frac{1}{2\pi} \int_0^{2\pi} s \cdot f(z_0 + se^{i\theta}) d\theta \\
\implies f(z_0) \int_0^r s ds &= \frac{1}{2\pi} \int_0^{2\pi} \int_0^r f(z_0 + se^{i\theta}) \cdot s ds d\theta \\
\implies \frac{1}{2} r^2 f(z_0) &= \frac{1}{2\pi} \iint_{D_r(z_0)} f(z) dA \\
\implies f(z_0) &= \frac{1}{\pi r^2} \iint_{D_r(z_0)} f(z) dA \\
\implies f(z_0) &= \frac{1}{2\pi} \int_0^{2\pi} f(z_0 + re^{i\theta}) d\theta.
\end{aligned}$$

Proposition 10.2 (Maximum in Interior Implies Constant).

Let f be holomorphic on Ω be open and connected, and suppose that there is a $z_0 \in \Omega$ such that

$$|f(z_0)| = \sup_{z \in \Omega} |f(z)|,$$

i.e. z_0 is a maximal point of f . Then f is constant on Ω .

If Ω is additionally **bounded**, then f is continuous on $\bar{\Omega}$, then

$$\sup_{z \in \bar{\Omega}} |f(z)| = \max_{z \in \bar{\Omega}} |f(z)|.$$

Proof.

Since $|f|$ is continuous and $\bar{\Omega}$ is compact, $|f|$ attains a maximum at some point in $\bar{\Omega}$. We want to show that if $|f(z_0)| = \sup_{z \in \Omega} |f(z)|$, then f is constant.

Assume that there exists a $z_0 \in \Omega$ such that $f(z) = f(z_0)$. Let $O = \{\xi \in \Omega \mid f(\xi) = f(z_0)\}$.

Claim 10.3. 1. O is not empty, since $z_0 \in O$.

2. O is closed, since if $\xi_n \rightarrow \xi$ then $f(\xi_n) = f(z_0)$ implies $f(\xi) = f(z_0)$ since f is continuous.

3. (**Claim**) O is open.

Suppose $\xi_0 \in O$, then there exists a disc $D_\rho(\xi_0) \subset \Omega$ such that

$$f(\xi_0) = \frac{1}{\pi \rho^2} \int_{D_\rho(\xi_0)} f(z) dA.$$

Then (claim) $|f(\xi_0)| \geq |f(z)|$ for all $z \in D_\rho(\xi_0)$, which forces $f(z) = f(\xi_0)$ for all $z \in D_\rho(\xi_0)$. ■

Proof (of the claim):

Suppose that $\sup_{\alpha \in \Omega} |f(z)| = |f(\xi_0)|$ and write $f(\xi_0) = Be^{i\alpha}$ for $B > 0$ and $\alpha \in \mathbb{R}$. Then define

$g(z) = f(z)e^{-i\alpha}$; then $g(\xi_0) = B$ is real, and thus

$$0 = g(\xi_0) - B = \frac{1}{\pi\rho^2} \iint_{D_\rho(\xi_0)} \Re(g(z) - B) \, dA.$$

Note that $\Re(g(z) - B) \leq 0$ implies that $\Re(g(z) - B) \equiv 0$ on $D_\rho(z_0)$, so we can write $g(z) = B + iI(z)$ for some real-valued function I .

But then $|g(z)|^2 = B^2 + I(z)^2 = B^2$ by the previous statement, and so $I(z) = 0$, forcing $g(z) = B$ and thus $f(z) = Be^{i\alpha}$. This shows that O is open, and thus $O = \Omega$. ■

10.2 Biholomorphisms of the Open Disc

Proposition 10.4 (*Biholomorphisms of the Open Disc are Contractions (Stein 2.1)*).

Suppose f is holomorphic on $D_1(0)$ and $|f(z)| \leq 1$ for all $|z| < 1$ with $f(0) = 0$. Then $|f(z)| \leq |z|$ for all $|z| < 1$.

Moreover, there is a point $z_0 \in D_1(0)$ such that $|f(z_0)| = |z_0|$ iff $f(z) = cz$ for some $c \in S^1$.

Proof.

Define

$$g(z) = \begin{cases} \frac{f(z)}{z} & z \neq 0 \\ f'(0) & z = 0 \end{cases}.$$

Then g is holomorphic on $D_1(0)$ and $|g(z)| \leq \frac{1}{\rho}$ for all $|z| < \rho < 1$. Now apply the maximum principle: since this is true for all $\rho < 1$, consider the limit $\rho \rightarrow 1^-$.

Then $|g(z)| \leq 1$, so $\left| \frac{f(z)}{z} \right| \leq 1$ and $|f(z)| \leq |z|$. If $|f(z_0)| = |z_0|$ for any point, then $|g(z_0)| = 1$ implies $g(z_0) = c$ and $c \in S^1$.

Thus $f(z) = cz$ for some $c \in S^1$. ■

Corollary 10.5 (*Characterization of Biholomorphisms of the Disc*).

Recall that

$$\Phi_a(z) := \frac{z - a}{1 - \bar{a}z}.$$

If $f : D_1(0) \rightarrow D_1(0)$ is a biholomorphism, then

$$f(z) = c\Phi_a(z) = e^{i\theta}\Phi_a(z)$$

So every such function is a rotated form of Φ_a .

Let Ω be a connected open domain and $f : \Omega \rightarrow \mathbb{C}$ holomorphic with $f \in C^1$. Then

$$\int_{\gamma} f(z) dz = 0$$

for every closed curve $\gamma \subset \Omega$, which implies that $f^{(k)}(z)$ exists for all $k \in \mathbb{N}$ and f is smooth/holomorphic.

10.3 Morera

Theorem 10.6 (Morera, Partial Converse to Cauchy's Integral Theorem).

Suppose $g : \Omega \rightarrow \mathbb{C}$ is continuous and $\int_{\gamma} g(z) dz = 0$ whenever $\gamma = \partial R$ for some rectangle $R \subset \Omega$ with sides parallel to the axes:

Then $g(z)$ is holomorphic in Ω .

Proof.

Fix a point $\alpha = a + ib$ and given $z = x + iy$, construct a rectangle R containing z . Then by assumption, $\int_{\partial R} g(z) dz = 0$. Let γ_{az} be the path given by traversing the bottom edge of R , and σ_{az} by the top path.

Let

$$\begin{aligned} f(z) &= \int_{\gamma_{\alpha z}} g(z) \, dz \\ &= \int_a^x g(s + ib) \, ds + i \int_b^y g(x + it) \, dt. \end{aligned}$$

Since

$$\int_{\partial R} g(z) \, dz = 0 = \int_{\gamma_{\alpha z}} \cdots - \int_{\sigma_{\alpha z}} \cdots,$$

we have

$$\begin{aligned} f(z) &= \int_{\sigma_{\alpha z}} g(z) \, dz \\ &= i \int_b^y g(a + it) \, dt + \int_x^a g(s + iy) \, ds. \end{aligned}$$

Exercise: Apply $\frac{\partial}{\partial y}$ to the first identity and $\frac{\partial}{\partial x}$ to the second.

This yields

$$\frac{\partial f}{\partial x} = g(z) \quad \text{and} \quad \frac{\partial f}{\partial y} = ig(z) = i \frac{\partial f}{\partial x}$$

by applying the FTC, which are precisely the Cauchy-Riemann equations for f . So f is holomorphic, and thus $f(z) = g(z)$. ■

11 Wednesday February 5th

11.1 Cauchy/Morera Theorems

Recall last time: We have Cauchy's theorem, which says that if $f : \Omega \rightarrow \mathbb{C}$ is holomorphic then

$$\int_{\gamma} f dz = 0.$$

We have a partial converse:

Theorem 11.1 (Morera).

If $g : \Omega \rightarrow \mathbb{C}$ is continuous and $\int_R g dz = 0$ for every rectangle $R \subset \Omega$ with sides parallel to the axes, then g is holomorphic.

Proof (Morera).

Fix a point $a \in \Omega$, then for any $z \in \Omega$ define $f(z) = \int_{\gamma_{a,z}} g(\xi) d\xi = \int_{\sigma_{a,z}} g(\xi) d\xi$.

Then $\frac{\partial f}{\partial z} = \frac{\partial f}{\partial x} = \frac{1}{i} \frac{\partial f}{\partial y} = g(z)$, making g holomorphic.

■

11.2 Schwarz Reflection

Theorem 11.2 (*Schwarz Reflection, Extending Holomorphic Functions Across Reflected Regions*).

Let $\Omega = \Omega^+ \cup L \cup \Omega^-$ be a region of the following form:

I.e., $L = \{z \in \Omega \mid \operatorname{im} z = 0\}$, $\Omega^\pm = \{\pm \operatorname{im} z > 0\}$ where Ω is symmetric about the real axis, i.e. $z \in \Omega \implies \bar{z} \in \Omega$.

Assume that $f : \Omega^+ \cup L \rightarrow \mathbb{C}$ is continuous and holomorphic in Ω^+ and real-valued on L . Define

$$g(z) = \begin{cases} f(z) & z \in \Omega^+ \cup L \\ \overline{f(\bar{z})} & z \in \Omega^- \end{cases}.$$

Then $g(z)$ is defined and holomorphic on Ω .

Proof (Schwarz Reflection).

Since g is C^1 in Ω^- , check that g satisfies the Cauchy-Riemann equations on Ω^- and thus holomorphic there. To see that g is holomorphic on all of Ω , we'll show the integral over every rectangle is zero.

It's clear that if $R \subset \Omega^\pm$, $\int_R g = 0$ since g is holomorphic there, so it suffices to check rectangles intersecting the real axis. Write $R = R^+ \cup R^-$:

We then have $R^+ = \lim_{\varepsilon \rightarrow 0} R_\varepsilon$ and $R^- = \lim_{\varepsilon \rightarrow 0} R_{-\varepsilon}$, and $\int_{R_{\pm\varepsilon}} g = 0$ for all $\varepsilon > 0$. By continuity of f on L , we have $\lim \int_{R_\varepsilon} g(z) dz = 0$. ■

11.3 Goursat's Theorem

Theorem 11.3 (Goursat, implies smooth).

If $f : \Omega \rightarrow \mathbb{C}$ is complex differentiable at each point of Ω , then f is holomorphic. I.e.,

$$f \in C^1(\Omega) \implies f \in C^\infty(\Omega).$$

Proof (Goursat).

We have $\int_R f dz = 0$ for all rectangles R . Write $I = \int_R f dz$. Break R into 4 sub-rectangles:

Then rewriting the integral and applying the triangle inequality yields

$$I = \int_R f = \sum_{j=1}^4 \int_{R_j} f = \sum_{j=1}^4 I_j \implies |I| \leq \sum_j |I_j|.$$

So for at least one j , we have $|I_j| \geq \frac{1}{4}|I|$; wlog call it R_1 . By continuing to subdivide, we can write

$$|I| \leq 4|I_k| = 4 \left| \int_{R_1} f \right| \leq 4 \left(4 \left| \int_{R_2} f \right| \right) \cdots \leq 4^k \left| \int_{R_k} f \right|.$$

This is a sequence of nested compact intervals, so there is some $z_0 \in \bigcap R_k$. Write $f(z) = f(z_0) + f'(z_0)(z - z_0) + \delta(z, z_0)$, and since

$$\lim_{z \rightarrow z_0} \frac{|\delta(z, z_0)|}{z - z_0} = 0,$$

we have $\delta(z, z_0) = o(z - z_0)$. Then $|I| \leq 4^k \frac{1}{2^k} |R|$. We then try to estimate the integral using the fact that $|\delta(z, z_0)| \leq \delta_k |z - z_0|$ for some constant $\delta_k \rightarrow 0$ as $k \rightarrow \infty$.

$$\begin{aligned}
\int_{R_k} f i &= \int f(z_0) + f'(z_0)(z - z_0) + \delta(z, z_0) \\
&= \int_{R_k} \delta(z, z_0) \quad \text{since the first two terms are holomorphic} \\
&\leq \frac{1}{2^k} |R| \delta_k \frac{C}{2^k} |R| \\
&= c/4^k |R|^2 \delta_k \\
&\xrightarrow{k \rightarrow \infty} 0,
\end{aligned}$$

where we use the fact that in R_k we have

$$\begin{aligned}
R_k = 2(x + y) &\implies R^2/4 = x^2 + y^2 + x + y \leq_{CS} x^2 + y^2 + x^2 + y^2 = 2(x^2 + y^2) \\
&\implies x^2 + y^2 \leq R^2/8 \implies L = \sqrt{x^2 + y^2} \leq R/\sqrt{8} \\
&\implies |z - z_0| \leq \sqrt{x^2 + y^2} \leq R_k/2\sqrt{2} \text{ and } R_k = \frac{1}{2^k}|R|.
\end{aligned}$$

Note that triangles implies rectangles, but think about how to use triangles to prove it for rectangles (note that sides should be parallel to axes!)

12 Friday February 7th

12.1 Sequences of Holomorphic Functions

Theorem 12.1 (*The Uniform Limit of Holomorphic Functions is Holomorphic*).

Suppose $\{f_n\} \rightarrow f$ is a sequence of holomorphic functions converging uniformly on any compact subset $K \subset \Omega$. Then f is holomorphic.

Proof.

Let D be any disc such that $\bar{D} \subset \Omega$. For any rectangle $R \subset D$, we have

$$\int_R f_n dz = 0.$$

Since $f_n \rightarrow f$ uniformly, $\int_R f dz = 0$ and thus f is holomorphic in D .

**Theorem 12.2 (Uniform Convergence of Derivatives).**

Under the same hypotheses, $f'_n \rightarrow f$ uniformly on any compact subset $K \subset \Omega$.

Proof.

See Stein. ■

Corollary 12.3 (When Functions Defined by Integrals are Holomorphic).

Suppose $F(z, s) : \Omega \times [a, b] \rightarrow \mathbb{C}$ and

1. $F(z, s)$ is holomorphic in z for each fixed $s \in [a, b]$.
2. $F(z, s)$ is continuous in $\Omega \times [a, b]$.

Then $f(z) = \int_a^b F(z, s) ds$ is holomorphic on Ω .

Proof.

Define $f_n(z) = \left(\sum_{k=1}^n F(z, s_k) \right) \frac{b-a}{n}$ where each $s_k = a + \frac{b-a}{n}k \in [a, b]$. Need to show $f_n(z)$ converges uniformly on any compact $K \subset \Omega$, i.e. it's uniformly Cauchy. Fix K compact, then

by a theorem in topology $K \times [a, b]$ is again compact.

Using the fact that F is continuous on a compact set and thus uniformly continuous, fix $\varepsilon > 0$ and find $\delta > 0$ such that $\max_{z \in K} |F(z, s) - F(z, t)| < \varepsilon$ for all $s, t \in [a, b]$ with $|t - s| < \delta$.

Thus if $\frac{b-a}{n} < \delta$ and $z \in K$, we have an estimate

$$\begin{aligned} |f_n(z) - f(z)| &= \left| \sum_{k=1}^n \int_{s_{k-1}}^{s_k} F(z, s_k) - F(z, s) \, ds \right| \\ &= \sum_{k=1}^n \int_{s_{k-1}}^{s_k} |F(z, s_k) - F(z, s)| \, ds \\ &\leq \varepsilon(b-a). \end{aligned}$$

Thus $f_n \xrightarrow{u} f$. ■

Remark: this is useful for showing

$$\Gamma(z) = \int_0^\infty e^{-s} s^{z-1} \, ds$$

is holomorphic for $\Re z > 0$.

12.2 Uniform Approximation

Question: can every function be uniformly approximated by polynomials?

Answer: in general, no. Take $f(z) = \frac{1}{z}$, which is holomorphic on $\mathbb{C} \setminus 0$, but $\int_\gamma P_N(z) = 0$ for any polynomial (since they are entire) for any loop γ around 0, but $\int_\gamma \frac{1}{z} = 2\pi i$.

Theorem 12.4 (Uniform Approximation by Polynomials (Stein 5.2)).

If f_n is a sequence of holomorphic functions converging uniformly on any compact subset K of Ω then f is holomorphic in Ω and if $f(z) = \sum a_n(z - z_0)^n$ then $P_N(z) = \sum_{n=0}^N a_n(z - z_0)^n$.

Theorem 12.5 (Uniform Approximation by Rational Functions (Stein 5.7)).

Any holomorphic function in a neighborhood of a compact set K can be approximated by a rational function with singularities only in K^c . If K^c is connected, it can be approximated by a polynomial.

Lemma 12.6 (5.8, ???).

Suppose f is holomorphic in an open set Ω with $K \subset \Omega$ compact. Then there exist finitely many segments $\{\gamma_i\}_{i=1}^N$ in $\Omega \setminus K$ such that for all $z \in K$, ???.

Proof (of Lemma, Idea).

Divide region into squares, take γ_i to be line segments such that they enclose K .

$$\begin{aligned} f(z) &= \frac{1}{2\pi i} \sum_{n=1}^N \int_{\omega_n} \frac{f(\xi)}{z - \xi} d\xi \\ &= \frac{1}{2\pi i} \int_{\Gamma} \frac{f(\xi)}{z - \xi} d\xi. \end{aligned}$$

where we can rewrite

$$\int_{\gamma_n} \dots = \int_0^1 \frac{f(\gamma_n(t))}{\gamma_n(t) - z_0} \gamma'_n(t) dt = \int_0^1 F(z, s) ds$$

The idea is that we can then write $\frac{1}{\xi - z} = \frac{1}{\xi} \frac{1}{1 - \frac{z}{\xi}} = \xi^{-1} \sum_k \left(\frac{z}{\xi}\right)^k$, which allows uniform approximation by polynomials. ■

13 Wednesday February 12th

13.1 Singularities

Let $f(z)$ be holomorphic on Ω , then we have Cauchy's integral formula:

$$f(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(\xi)}{\xi - z} d\xi.$$

Example: Note that $f(z) = \frac{1}{z}$ is holomorphic on $\mathbb{C} \setminus 0$.

Let Ω be an open set containing a disk D and $\Omega \setminus p$ be a punctured domain.

Definition 13.0.1 (Isolated Singularities).

We say f has an *isolated singularity* at p iff f is defined and holomorphic on some deleted neighborhood of p .

Classification of singularities:

1. **Removable:** $|f(z)|$ is bounded on some $D_r(p) \setminus p$.

Example: $f(z) = \sin(z)/z$.

2. **Poles:** $\lim_{z \rightarrow p} |f(z)| = \infty$.

Example: $f_n(z) = \frac{1}{z^n}$ at $p = 0$

3. **Essential:** neither 1 nor 2.

Example: $f(z) = e^{\frac{1}{z}}$ at $z = 0$.

Note that for singularities at ∞ , we can just make the change of variables $z \mapsto \frac{1}{z}$. Defining $F(z) = f(\frac{1}{z})$, the singularities at 0 of f correspond to singularities at infinity for F .

13.2 Spherical Projection

We can solve for a spherical projection map $S^2 \rightarrow \mathbb{C}$. Let $(0, 0, 1)$ be the North pole of the sphere; then to map to $(x, y, 0)$ on the plane we can take the parameterization $\ell : (tx, ty, 1 - t)$. This yields

$$t \mapsto \left(\frac{2\Re(z)}{1 + |z|^2}, \frac{2\Im(z)}{1 + |z|^2}, 1 - \frac{2}{1 + |z|^2} \right).$$

From this we can induce a spherical metric:

$$\phi(z_1, z_2) = \frac{z|z_1 - z_2|}{\sqrt{|z_1|^2 + 1}\sqrt{|z_2|^2 + 1}}.$$

Proposition 13.1 (*Continuous Extension Over Removable Singularities*).

Let p be a removable singularity of f . Then

1. $\lim_{z \rightarrow p} f(z)$ exists.
2. The function

$$\tilde{f}(x) = \begin{cases} f(z) & z \neq p \\ \lim_{z \rightarrow p} f(z) & z = p \end{cases}.$$

is holomorphic on $D_r(p)$.

Example 13.1.

Consider

$$\frac{\sin(z)}{z} \xrightarrow{z \rightarrow 0} 1.$$

Proof (of Proposition).

Take $p = 0$ and consider $g(z) = z^2 f(z)$. We can verify directly that g satisfies the Cauchy-Riemann equations on $D_r(0)$. Then g is holomorphic on $D_r(0)$ and vanishes to order 2 at $z = 0$, and

$$f(z) = \frac{g(z)}{z^2}$$

is holomorphic on $D_r(0)$.

If $f(z)$ has a pole at z_0 , then $\lim_{z \rightarrow z_0} |f(z)| \rightarrow \infty$ by definition, iff $\lim_{z \rightarrow z_0} \frac{1}{|f(z)|} = 0$ and thus the reciprocal has a zero at $z = z_0$. If z_0 is a zero of a nontrivial holomorphic function f , then z_0 is isolated, i.e. there exists a punctured disc $D_r(z_0) \setminus z_0$ on which f is nonzero. ■

Theorem 13.2(???)

If f is holomorphic in a connected domain Ω with a zero z_0 , then there exists a non-vanishing holomorphic function $g(z)$ and some $n \in \mathbb{N}$ such that

$$f(z) = (z - z_0)^n g(z)$$

Proof.

Since f is holomorphic, expand its power series $f(z) = \sum a_k (z - z_0)^k$. Since $f(z_0) = 0$, we have $a_0 = 0$. Choose the smallest n such that $a_n \neq 0$, so

$$\begin{aligned} f(z) &= a_n (z - z_0)^n + a_{n+1} (z - z_0)^{n+1} + \cdots \\ &= (z - z_0)^n (a_n + \cdots) \\ &:= (z - z_0)^n g(z). \end{aligned}$$

Then $g(z_0) \neq 0$, so by continuity there exists an r such that $|g(z)| \geq |a_n|/2$. ■

Definition 13.2.1 (Pole).

A function f defined on a deleted neighborhood of z_0 has a **pole** at z_0 if the function $F = \frac{1}{f}$ with $F(z_0) := 0$ is holomorphic in a full neighborhood of z_0 .

14 Friday February 14th

14.1 Defining Residues

Interesting open problems: dynamical systems on \mathbb{C}^2 .

If f is holomorphic in Ω with $f(z_0) = 0$ then there exists a disc on which $f(z) = \sum a_n(z - z_0)^n$ where $a_0 = f(z_0) = 0$. There is then a minimal k such that $f(z) = (z - z_0)^k g(z)$ where $g(z_0) \neq 0$; this k is the *order* of the zero a_0 .

Recall the definition of a *pole*: A function defined in a deleted neighborhood of z_0 has a *pole* at z_0 iff $F = \frac{1}{f}$ with $F(z_0) := 0$ is holomorphic in a full neighborhood of z_0 .

Theorem 14.1 (*Extraction of Holomorphic Part*).

If f has a pole at z_0 , then there exists a holomorphic function h and a unique k such that $f(z) = (z - z_0)^{-k} h(z)$.

Proof .

Write

$$\frac{1}{f} = (z - z_0)^k g(z)$$

with $g(z_0) \neq 0$. Then there is an r such that $|g(z)| \geq \frac{1}{2}|g(z_0)|$ in a disc about z_0 . Then

$$f(z) = \frac{1}{(z - z_0)^k g(z)} := (z - z_0)^{-k} h(z)$$

where $h = 1/g$.

We can then write

$$f(z) = \left(\sum_{i=0}^{k-1} b_i (z - z_0)^{-i} \right) + b_k + \sum_{i=1}^{\infty} b_{k+i} (z - z_0)^i$$

for some fixed k , where $\sum b_i (z - z_0)^i$ is the power series expansion of h . Write this as

$P(z) + G(z)$ where $G(z) = \sum_{i=0}^{\infty} b_{i+k} (z - z_0)^i$. Denote P the *principal part* of f at the pole $z = z_0$.

Note that

$$\int_{D_r(z_0)} f = \int_{D_r(z_0)} P(z) = 2\pi i a_{-1}.$$

■

Definition 14.1.1 (Residue).

The coefficient a_{-1} is referred to as the *residue* of f at $z = z_0$.

14.2 Residues

Note that

$$\int \frac{1}{(z - z_0)^k} = \begin{cases} 2\pi i & k = 1 \\ 0 & \text{else} \end{cases}.$$

Residues can be computed using the following formula:

$$a_{-1} = \frac{1}{2\pi i} \int_{D_r(z_0)} f. \quad (1)$$

Theorem (Residue Formula) :

$$\text{Res}_{z=z_0} f = \lim_{z \rightarrow z_0} \frac{1}{(k-1)!} \left(\frac{\partial}{\partial z} \right)^{k-1} (z - z_0)^k f(z).$$

Proof .

Expand in power series, direct check. ■

A useful special case: if z_0 is a pole of order 1, then

$$\text{Res}_{z=z_0} f = \lim_{z \rightarrow z_0} (z - z_0) f(z).$$

A useful formula:

$$\frac{1}{2\pi i} \int_{\Gamma(z_0)} f = \text{Res}_{z=z_0} f.$$

Theorem 14.2 (Integral Residue Theorem).

Suppose that f is holomorphic in an open set containing a toy contour γ and its interior except for finitely many poles $\{z_i\}$. Then

$$\frac{1}{2\pi i} \int_{\gamma} f = \sum \text{Res}_{z=z_i} f(z).$$

Proof .

Omitted to cover some material needed for homework. ■

Note that if f has a pole of order k , we can expand it in *Laurent series* as

$$\sum_{n=-k}^1 a_n(z-z_0)^n + \sum_{n=0}^{\infty} a_n(z-z_0)^k.$$

How to determine the radius of convergence of a Laurent series:

$$\sum_{n=-\infty}^{\infty} a_n z^n = \sum_{n \in \mathbb{N}} c_n z^n + \sum_{n \in \mathbb{N}} d_n z^{-n}.$$

Applying the root test,

$$\begin{aligned} \limsup_n |c_n(z-a)|^{1/n} &< 1 \\ \iff \limsup_n |c_n|^{1/n} |z-a| &< 1 \\ \iff |z-a| &\leq \frac{1}{\limsup_n |c_n|^{1/n}} := \rho_1. \end{aligned}$$

Similarly, we need

$$\rho_2 := \limsup_n |d_n|^{1/n} < |z-a|.$$

If $\rho_1 > \rho_2$, this will converge on an annulus.

15 Monday February 17th

See Hans Lewy 1957 Annals, Folland and Stein 1973. Does a linear system of PDEs with analytic functions have an analytic solution? What about just C^∞ ?

15.1 Getting a Holomorphic Function from a Laurent Series

We can write a formal series

$$\begin{aligned} f(z) &= \sum_{n \in \mathbb{Z}} a_n (z-a)^n \\ &= \sum_{n \geq 0} a_n (z-z_0)^n + \sum_{n \leq -1} a_n (z-z_0)^n \\ &:= A(z) + B(z). \end{aligned}$$

Part A converges for

$$|z-a| < R_1 = \left(\limsup_n |a_n|^{1/n} \right)^{-1}.$$

Part B converges for

$$|z - a| > R_2 = \limsup |c_{-n}|^{1/n}.$$

If $R_1 < R_2$, this does not converge. Note that if $R_1 > R_2$, then f converges and defines a holomorphic function on the annulus $R_2 < |z - a| < R_1$. Moreover, f converges uniformly on any compact subset of this annulus, so it can be differentiated term-by-term, and the derivative has the same region of convergence.

Note that if f equals its Laurent expansion, then

$$c_n = \frac{f^{(n)}(a)}{n!} = \frac{1}{2\pi i} \int_{\gamma} \frac{f(\xi)}{(\xi - a)^{n+1}} dz$$

where γ is contained in the annulus of convergence, and $c_{n \leq -1} = 0$.

We also have

$$\begin{aligned} \frac{1}{2\pi i} \int_{\gamma} \frac{f(z)}{(z - a)^m} dz &= \sum_{n \in \mathbb{Z}} \frac{c_n}{2\pi i} \int_{\gamma} \frac{1}{(z - a)^{m-n}} dz \\ &= c_{m-1}, \end{aligned}$$

since

$$\int_{\gamma} \frac{1}{(z - a)^k} dz = \begin{cases} 2\pi i & k = 1 \\ 0 & \text{else} \end{cases},$$

we have the following formula for the coefficients:

$$c_m = \frac{1}{2\pi i} \int_{\gamma} \frac{f(z)}{(z - a)^{m+1}} dz. \quad (2)$$

So we can start with a series and get a holomorphic function on some region.

15.2 Obtaining a Laurent Series from a Holomorphic Function

We can also start with a holomorphic function and get a Laurent series. Suppose f is holomorphic on an annulus $R_2 < |z| < R_1$. We can then write

$$f(z) = \frac{1}{2\pi i} \int_{|w-a|=R_1} \frac{f(w)}{w - z} dw - \int_{|w-z|=R_2} \frac{f(w)}{w - z} dw$$

Since $|z - a|/|w - a| < 1$, we have

$$\begin{aligned}
 \frac{1}{2\pi i} \int_{|w-a|=R_1} \frac{f(w)}{w-z} dz &= \frac{1}{2\pi i} \int_{|w-a|=R_1} \frac{f(w)}{(w-a) - (z-a)} dz \\
 &= \frac{1}{2\pi i} \int_{|w-a|=R_1} \frac{f(w)}{(w-a)} \sum_{n \in \mathbb{N}} \frac{(z-a)^n}{(w-a)^n} dz \\
 &= \sum_{n \in \mathbb{N}} (z-a)^n \frac{1}{2\pi i} \int_{|w-a|=R_1} \frac{f(w)}{(w-a)^{n+1}} dw \\
 &= \sum_{n \in \mathbb{N}} c_n (z-a)^n.
 \end{aligned}$$

Similarly,

$$\begin{aligned}
 -\frac{1}{2\pi i} \int_{|w-a|=R_2} \frac{f(w)}{w-z} dw &= -\frac{1}{2\pi i} \int_{|w-a|=R_2} \frac{f(w)}{(w-a)-(z-a)} dw \\
 &= -\frac{1}{2\pi i} \frac{1}{z-a} \int_{|w-a|=R_2} \frac{f(w)}{\frac{w-a}{z-a} - 1} dw \\
 &= \frac{1}{2\pi i} \frac{1}{z-a} \int_{|w-a|=R_2} \frac{f(w)}{1 - \frac{w-a}{z-a}} dw \\
 &= \frac{1}{2\pi i} \frac{1}{z-a} \int_{|w-a|=R_2} f(w) \sum_{n \in \mathbb{N}} \frac{(w-a)^n}{(z-a)^n} dw \\
 &= \sum_{n \in \mathbb{N}} \frac{1}{2\pi i} \frac{1}{(z-a)^{n+1}} \int_{|w-a|=R_2} f(w)(w-a)^n dw \\
 &= \sum_{n=-\infty}^{-1} c_n (z-a)^n.
 \end{aligned}$$

This yields a formula

$$c_m = \frac{1}{2\pi i} \int_{\gamma} \frac{f(z)}{(z-a)^{m+1}} dz. \quad (3)$$

In practice, we don't use this formula for extracting coefficients.

Example 15.1.

Let $f(z) = \frac{1}{z(z-1)}$. This has four Laurent series.

Let $C(a, R_1, R_2)$ be the annulus centered at a . Then at $C(0, 0, 1) = \mathbb{D} \setminus \{0\}$, we have

$$f(z) = \frac{1}{z} \frac{1}{1-z} = -\frac{1}{z} \sum_{k \in \mathbb{N}} z^k.$$

In $C(1, 1, 0) = \mathbb{D}(1, 1) \setminus \{1\}$, we have

$$\begin{aligned}
 f(z) &= \frac{1}{z-1} \frac{1}{z} \\
 &= \frac{1}{z-1} \frac{1}{1+(z-1)} \\
 &= \frac{1}{z-1} \sum_{k \in \mathbb{N}} (-1)^k (z-1)^k.
 \end{aligned}$$

In $C(0, 1, \infty)$, we can write

$$\begin{aligned} f(z) &= \frac{1}{z^2} \frac{1}{1 - \frac{1}{z}} \\ &= \frac{1}{z^2} \sum_{k \in \mathbb{N}} \frac{1}{z^k}. \end{aligned}$$

And in $C(1, 1, \infty)$ we have

$$f(z) = \frac{1}{z-1} \frac{1}{z-1+1}.$$

16 Friday February 21st

16.1 Singularities

Recall that there are three types of singularities:

- Removable
- Poles
- Essential

Recall that a function g is holomorphic at z_0 iff

$$\lim_{z \rightarrow z_0} (z - z_0)g(z) = 0$$

Theorem 16.1(3.2).

An isolated singularity z_0 of f is a pole $\iff \lim_{z \rightarrow z_0} f(z) = \infty$.

Theorem 16.2(3.3, Casorati-Weierstrass).

If f is holomorphic in $D_r(z_0) \setminus \{z_0\}$ and has an essential singularity z_0 , then there exists a radius r such that $f(D_r(\{z_0\}) \setminus \{z_0\})$ is dense in \mathbb{C} .

Proof.

Proceed by contradiction. Suppose there exists a $w \in \mathbb{C}$ and a $\delta > 0$ such that

$$D_\delta(w) \cap f(D_r(\{z_0\}) \setminus \{z_0\}) = \emptyset.$$

If $z \in D_r(w) \setminus z_0$, then $|f(z) - w| > \delta$. Define $g(z) = \frac{1}{f(z) - w}$ on $D_r(z_0) \setminus \{z_0\}$; then $|g(z)| < \frac{1}{\delta}$.

Note that this implies that $g(z)$ is holomorphic on $D_r(z_0) \setminus \{z_0\}$. $g(z)$ being holomorphic here follows from f being holomorphic here.

Then $g(z)$ has a removable singularity at $z = z_0$ by theorem 3.1.

If $g(z_0) \neq 0$, then $f(z) - w$ is holomorphic at z_0 , contradicting the fact that z_0 is an essential singularity.

If instead $g(z_0) = 0$, then z_0 is a pole, again a contradiction. ■

Note: revisit why this is a contradiction.

16.2 Singularities at Infinity

The point $z = \infty$ can be one of three types of singularities:

1. *Removable* $\iff f(z) = \sum_{k=-1}^{\infty} c_k \frac{1}{z^k}$.
 - I.e. only one positive exponent.
2. *Pole* $\iff f(z) = \sum_{k=-\infty}^n c_k z^k$
 - I.e. there are finitely many positive exponents.
3. *Essential* $\iff f(z) = \sum_{k=-\infty}^{\infty} c_k z^k$
 - There are infinitely many positive exponents.

Definition 16.2.1 (Meromorphic).

A function f is **meromorphic** on Ω iff there exists a sequence $\{z_i\} \subset \Omega$ with no limit point in Ω such that

1. f is holomorphic on $\Omega \setminus \{z_i\}$, and
2. f has poles at each z_i .

Theorem 16.3(3.4, Meromorphic Functions are Rational).

f is meromorphic on \mathbb{CP}^1 iff f is a rational function.

Proof.

\implies : By part 1 of the definition above, the point $z = 0$ is either a pole or a removable singularity of the function $F(z) = f\left(\frac{1}{z}\right)$. By part 2, F has finitely many poles $\{z_k\}_{k=1}^N$. So for each k , write

$$f(z) = f_k(z) + g_k(z)$$

where f_k is the principal part and g_k is holomorphic in a neighborhood of z_k . Then $f_k(z)$ is a polynomial in $\left(\frac{1}{z - z_k}\right)$, say of degree m_k . But then

$$F(z) := f\left(\frac{1}{z}\right) = \tilde{f}_{\infty}(z) + \tilde{g}_{\infty}(z)$$

where $\tilde{f}_{\infty}(z)$ is a polynomial in z , and $\tilde{g}_{\infty}(z)$ is holomorphic near zero. Thus $\tilde{f}_{\infty}\left(\frac{1}{z}\right)$ is a polynomial in $\frac{1}{z}$.

Define $f_\infty(z) = \tilde{f}_\infty\left(\frac{1}{z}\right)$ and

$$H(z) = f(z) - f_\infty(z) - \sum_k f_k(z).$$

Then H is entire and bounded and thus constant, and since $\lim_{z \rightarrow \infty} H(z) = 0$, H is identically zero. Thus

$$f(z) = f_\infty(z) + \sum_k f_k(z)$$

\Leftarrow : To be continued, uses the argument principle, Rouché's theorem, and Jordan's lemma. ■

17 Wednesday February 26th

17.1 Argument Principle and Application

Let f be holomorphic in Ω which is open, simple, and connected. Then $f(z_0) = 0$ implies there exists an integer m such that $f(z) = (z - z_0)^m g(z)$ where $g(z_0) \neq 0$.

Let $N_\Omega(f)$ be the number of zeros of f inside Ω , and $N_\Omega(f, a)$ be the number of zeros of $f - a$ in Ω . Writing $f = f_1 f_2$ where $f_1 = (z - z_0)^m$ and $f_2 = g(z)$, we have

$$\begin{aligned} \frac{f'}{f} &= \frac{f'_1}{f_1} + \frac{f'_2}{f_2} \\ &= \frac{m}{z - z_0} + \frac{g'}{g}. \end{aligned}$$

Now integrating both sides yields

$$\frac{1}{2\pi i} \int_{D_r(z_0)} \frac{f'(z)}{f(z)} dz = m,$$

so the integral of this function counts the number of zeros of f in $D_r(z_0)$.

Proposition 17.1 (Argument Principle).

Let f be holomorphic in a neighborhood of $\overline{D_r(z_0)}$ and suppose that f is non-vanishing on all of $\partial D_r(z_0)$. Then

$$\frac{1}{2\pi i} \int_{D_r(z_0)} \frac{f'(z)}{f(z)} dz = N_{D_r(z_0)}(f).$$

More generally, if $q(z)$ is another holomorphic function in a neighborhood of $\overline{D_r(z_0)}$ and z_1, \dots, z_k are the distinct zeros of f in $D_r(z_0)$ with orders m_1, \dots, m_k , then

$$\frac{1}{2\pi i} \int_{D_r(z_0)} q(z) \frac{f'(z)}{f(z)} dz = \sum_{j=1}^k q(z_j) m_j.$$

Proof .

Write $f(z) = \prod_{j=1}^k (z - z_j)^{m_j} g(z)$. By Leibniz's rule, if $h = f_1 \cdots f_\ell$, then

$$\begin{aligned} \frac{h'}{h} &= \sum_{j=1}^{\ell} \frac{f'_j}{f_j} \\ \implies q \frac{f'}{f} &= 1 \frac{g'}{g} + \sum_{j=1}^k \frac{m_j q}{z - z_j}. \end{aligned}$$

Since $\frac{g'}{g}$ is holomorphic in the closed disc, integrating both sides yields the desired formula.

Note that if we replace f by a family f_t of continuous functions, an integer-valued continuous function must be constant.

Corollary 17.2.

Let $f_t(z)$ for $0 \leq t \leq 1$ be a family of holomorphic functions on $D_{r+\varepsilon}(z_0)$ for some $\varepsilon > 0$. Suppose $f_t(z)$ is continuous for all z in this disc, uniformly in z , and for all t , $f_t(z)$ is nonvanishing on the boundary.

Then the following integral is independent of t :

$$\frac{1}{2\pi i} \int_{D_r(z_0)} \frac{f'_t(z)}{f_t(z)} dz.$$

Theorem 17.3 (Rouché's Theorem).

Let f, g be holomorphic in a neighborhood of $\overline{D_r(z_0)}$ and suppose that on $\partial D_r(z_0)$ we have

$$|f(z) - g(z)| < |f(z)| + |g(z)|.$$

Then f and g are nonvanishing on $\partial D_r(z_0)$ and

$$N_{D_r(z_0)}(f) = N_{D_r(z_0)}(g). \quad (4)$$

Proof .

If $f(w) = 0$ for some $w \in \partial D_r(z_0)$, then $|-g(w)| = |g(w)|$, but this contradicts condition ??.

■

So let $t \in [0, 1]$ with $f_t(z) = (1 - t)f(z) + tg(z)$. Then (claim) f_t is nonvanishing on the boundary, so we can apply the previous corollary.

Suppose otherwise that there exists w on the boundary such that $f_t(w) = 0$ for some t , so $(1 - t)f(w) + tg(w) = 0$. Then rearranging terms yields

$$\begin{aligned} f(w) &= t(g(w) - f(w)) \\ g(w) &= (1 - t)(g(w) - f(w)). \end{aligned}$$

But then

$$\begin{aligned} |f(w) + g(w)| &= t|g(w) - f(w)| + (1 - t)|g(w) - f(w)| \\ &= |g(w) - f(w)|, \end{aligned}$$

which contradicts condition ??

By the corollary, the integral is continuous in t and integer-valued, and thus constant.

Corollary 17.4 (Fundamental Theorem of Algebra).

Let $p(z) = \sum_{j=1}^n a_j z^j$ be a polynomial of degree n , so $a_n \neq 0$. Let $f(z) = a_n z^n$ and $g(z) = p(z)$.

If

$$|z| > \frac{|a_0| + \cdots + |a_m|}{|a_n|} > 1$$

then

$$\begin{aligned} |f(z) - g(z)| &= |a_0 + \cdots + a_{n-1} z^{n-1}| \\ &\leq |z|^{n-1} (|a_0| + \cdots + |a_{n-1}|) \\ &< |a_n| |z|^n \\ &= |f| \\ &\leq |f| + |g|. \end{aligned}$$

Note that this is useful because it tells you where the zeros are, namely in the disc $|z| < \frac{\sum |a_i|}{|a_n|}$.

Example 17.1.

Let $p(z) = 9 - 8z + 20z^2$, then all of the zeros are in a disc of radius $r = \frac{7}{4}$.

Qual alert: problems about power series, Rouché's, linear mapping, integration.

Example 17.2.

Let $f(z) = z^9 - 2z^6 + z^2 - 8z - 2$.

How many zeros are in the unit disc? Take $g(z) = -8z$, the largest term. Then $|f(z) - g(z)| \leq 1 + 2 + 1 + 2 = 6 < |f| + |g| = 8$, so condition ?? is satisfied. Thus they both have the same number of zeros, but g has exactly one zero.

What about $|z| = 2$? Then set $g(z) = z^9$, then check $|f(z) - z^9| \leq 150 < 152$, so all 9 zeros lie in this disc.

Exercise Let $g(z) = z^4 - 4z - 5$, how many zeros are in $|z| \leq 1$? Note the root on the boundary.

18 Friday February 28th

18.1 Rouché, Open Mapping, and Maximum Modulus

Theorem 18.1 (Rouché's Theorem).

Suppose f, g are holomorphic in $D_r(z_0)$ and $|f(z)| > |g(z)|$ on $\partial D_r(z_0)$. Then f and $f + g$ have the same number of zeros in $D_r(z_0)$.

Proof.

Let $f_t(z) = f(z) + tg(z)$ and use the argument principle. ■

Theorem 18.2 (Open Mapping Theorem (Stein 4.4)).

If f is holomorphic and nonconstant then f is an open map.

Proof.

Let $w_0 \in \text{im}(f)$ and say $f(z_0) = w_0$. We want to show that all w near w_0 are also in $\text{im}(f)$. Define $g(z) = f(z) - w = f(z) - w_0 + w_0 - w := F(z) + G(z)$. ■

Now choose $\delta > 0$ such that $D_\delta(z_0) \subset \Omega$ and $f(z) \neq w_0$ on $\partial D_\delta(z_0)$. We then select δ such that $|f(z) - w_0| \geq \varepsilon > 0$ on $\partial D_\delta(z_0)$. We have $|F(z)| = |f(z) - w_0| \geq \varepsilon$.

Now choose w such that $|G(z)| = |w - w_0| < \varepsilon$, noting that $G(z)$ is a constant function (?). Then $|F(z)| \geq \varepsilon > |w - w_0| = |G(z)|$. So apply Rouché's theorem and conclude that there exists $z \in D_\delta(z_0)$ such that $f(z) = w$.

Qual alert, some questions related to the Open Mapping Theorem.

Theorem 18.3 (Stein 4.5: Maximum Modulus).

If f is holomorphic and nonconstant on Ω , then $|f|$ can not attain a maximum in Ω .

Proof.

Suppose toward a contradiction that $|f|$ attains a maximum in Ω , say at z_0 . Since f is holomorphic, it is an open mapping, and therefore if $D_\delta(z_0) \subset \Omega$ then $f(D_\delta(z_0))$ contains a disc. Thus there exists a $z \in D_\delta(z_0)$ such that $|f(z)| > |f(z_0)|$. But this contradicts maximality of f at z_0 . ■

Corollary 18.4.

If $|f(z)| = 0$ on ∂U and f is nonconstant, then f has a zero in U .

Proof.

Let $c = |f(z)|$ for $z \in \partial U$. Suppose that $f(z)$ has no zeros in U . Then $g(z) = \frac{1}{f(z)}$ is continuous and holomorphic in U . Then for all $z_0 \in U$, $|g(z)| = \frac{1}{|f(z)|} = \frac{1}{|f(z_0)|} > \frac{1}{c}$, since $c = |f(z)|$ for $z \in \partial U$ implies $|f(z_0)| < c$. But this contradicts the maximum principle. ■

Proof technique: use the fact that the reciprocal is holomorphic. Note that this is stronger than f just being smaller in the interior, the modulus actually takes on the smallest value.

18.2 The Complex Logarithm

For $x > 0$, we define $\log(x) = \int_1^x \frac{1}{t} dt$, which is the inverse of e^x . For $z \neq 0$, we'd like to define $\log(z) = \log(re^{i\theta}) = \log(r) + i\theta$, but the argument θ is not uniquely defined.

Theorem 18.5 (Existence of Logarithm).

Suppose Ω is simply connected with $1 \in \Omega$ and $0 \notin \Omega$. Then in Ω , there is a branch of the logarithm $F(z) = \log_\Omega(z)$ such that

1. $F(z)$ is holomorphic on Ω .
2. $e^{F(z)} = z$ for all $z \in \Omega$
3. $F(r) = \log(r)$ for all $r > 0 \in \mathbb{R}$ near 1.

Proof.

Part 1:

We define $F(z)$ as a primitive of the function

$$F(z) = \int_\gamma \frac{1}{w} dw.$$

where γ is any curve in Ω connecting 1 and z . We have

$$\frac{dF}{dz} = \frac{1}{z} = \lim_{h \rightarrow 0} \frac{F(z+h) - F(z)}{h}.$$

Noting that $F(z+h) - F(z) = \int_\eta \frac{1}{w} dw$, we can parameterize η as $w = (1-s)z + s(z+h) = z + sh$.

Then

$$\begin{aligned}
\int \eta \frac{1}{w} dw &= \int_0^1 \frac{1}{z+sh} h ds \\
\Rightarrow \frac{1}{h} \int_0^1 \frac{1}{w} dw &= \int_0^1 \frac{1}{z+sh} ds \\
&= \int_0^1 \left(\frac{1}{z} + \frac{1}{z+sh} - \frac{1}{z} \right) ds \\
&= \frac{1}{z} - \frac{h}{z} \int_0^1 \frac{d}{z+sh} ds \\
&\xrightarrow{h \rightarrow 0} \frac{1}{z}.
\end{aligned}$$

Part 2:

Note that $\left(ze^{F(z)}\right)' = e^{F(z)} + ze^{-F(z)}\left(-\frac{1}{z}\right) = 0$.

Part 3:

To do. ■

Next time: once we have the log we can say more about the argument principle.

19 Friday March 6th

19.1 The Fourier Transform

Recall $\hat{f}(\xi) = \int_{\mathbb{R}} f(x) e^{2\pi i x \cdot \xi} dx$. Define $\mathcal{F}_a = ??$.

Definition 19.0.1 (Decay).

$f \in \mathcal{F}_a$ iff 1. f is holomorphic in the strip $S_a = \{z = x + iy \mid |y| < a\}$. 2. There exists an $A > 0$ such that $|f(x + iy)| < \frac{A}{1 + x^2}$.

Examples:

- $e^{-z^2} \in \mathcal{F}_a$ for all a
- $\frac{1}{c^2 + z^2} \in \mathcal{F}_a$ for all $a > c$
- $\frac{1}{\cosh(\pi z)} \in \mathcal{F}_a$ for $a < \frac{1}{2}$.

Lemma 19.1.

If $f \in \mathcal{F}_a$, then $f^{(n)}(z) \in \mathcal{F}_b$ for all $b < a$.

Theorem 19.2 (Boundedness of ?? Functions).

If $f \in \mathcal{F}_a$, then $|\hat{f}(\xi)| \leq B e^{-2\pi b|\xi|}$ for some constants b, B .

Proof .

If $\xi = 0$,

$$\begin{aligned} |\hat{f}(\xi)| &= \left| \int_{\mathbb{R}} f(x) e^{2\pi i x \cdot \xi} \right| \\ &\leq \int_{\mathbb{R}} |f(x)| \, dx \\ &\leq A \int_{\mathbb{R}} \frac{1}{1+x^2} \, dx \\ &= A\pi. \end{aligned}$$

For $\xi > 0$, integrate over the box $[-R, R] \times i[-b, 0]$:

Define $g(z) = f(z)e^{-2\pi i z \cdot \xi}$. The integral over the rectangle is zero, since g is holomorphic, so we can equate

$$\int_R^{R-ib} f(z) e^{-2\pi i z \cdot \xi} \, dz = \int_0^b f(R - it) e^{-2\pi i (R - it) \cdot \xi} (-i) \, dt$$

We can use the estimate in \mathcal{F}_a to obtain

$$\begin{aligned} \int_0^b \dots &\leq \int_0^b \frac{A}{1+R^2} e^{-2\pi s \xi} \, ds \\ &\leq O(R^{-2}). \end{aligned}$$

Then

$$\begin{aligned} \int_{\mathbb{R}} f(x) e^{-2\pi i x \cdot \xi} \, d\xi &= \int_{-\infty - ib}^{\infty - ib} \dots \, dz \\ &= \int_{\mathbb{R}} f(x - ib) e^{2\pi i (x - ib) \cdot \xi} \, dx \\ &\leq \int_{\mathbb{R}} \frac{A}{1+x^2} e^{-2\pi b \xi} \, dx \\ &= A\pi e^{-2\pi b \xi}, \end{aligned}$$

so we can take $B = A\pi$.

For $\xi > 0$, the same argument works with the rectangle above the axis. ■

19.2 Fourier Inversion

Theorem 19.3 (Fourier Inversion).

If $f \in \mathcal{F}_a$, then $f(x) = \int \hat{f}(\xi) e^{2\pi i x \cdot \xi} d\xi$.

Proof.

Letting $L_1 = \{x - ib\}$ and $L_2 = \{x + ib\}$

$$\begin{aligned}
 I &= \int_0^\infty \hat{f} \cdots + \int_{-\infty}^0 \hat{f} \cdots \\
 &= \int_0^\infty e^{2\pi i x \cdot \xi} \left(\int_{L_1} f(z) + e^{-2\pi i z \cdot \xi} dz \right) d\xi + \int_{-\infty}^0 e^{2\pi i x \cdot \xi} \left(\int_{L_1} f(z) + e^{-2\pi i z \cdot \xi} dz \right) d\xi \\
 &= \int_{L_1} \int_0^\infty e^{2\pi i x \cdot \xi - 2\pi i (s-ib)\xi} d\xi ds + \int_{L_2} f(z) \int_{-\infty}^0 e^{2\pi i x \cdot \xi - 2\pi i (s+ib)\xi} d\xi ds \\
 &\quad \text{by absolute convergence, where } z = s - ib \\
 &= \int_{L_1} f(z) \int_0^\infty e^{2\pi i (x-s+ib)\xi} d\xi ds + \int_{L_2} f(z) \int_{-\infty}^0 e^{2\pi i (x-s+ib)\xi} d\xi ds \\
 &= \int_{L_1} f(z) \frac{1}{2\pi i (x - i + ib)} ds + \int_{L_2} f(z) \frac{1}{2\pi i (x - s - ib)} \\
 &= \frac{1}{2\pi i} \int \frac{f(z)}{z - x} dz \\
 &= f(x),
 \end{aligned}$$

noting that

$$\int_0^\infty e^{as} ds = \frac{1}{a} \quad \text{for } \Re(a) > 0.$$

■

Note the similar trick: for $\xi < 0$, move up, and $\xi > 0$ move down to form a rectangle. Use the fact that integration along the vertical edges is zero.

20 Monday March 30th

20.1 Conformal Equivalence

We'll be following Stein, around Chapter 8 currently but skip section 4. We'll discuss Kobe's proof of the Riemann Mapping Theorem.

Definition 20.0.1.

A bijective holomorphic function $f : U \rightarrow V$ is called a *conformal map* or *biholomorphism*. Given such a map, we say that U and V are *conformally equivalent* or *biholomorphic*.

Note that this gives an equivalence relation on subsets of \mathbb{C} .

Proposition 20.1(1.1).

If $f : U \rightarrow V$ is holomorphic and injective, then for every $z \in U$, $f'(z) \neq 0$. In particular, the inverse of f defined on its image is holomorphic, and thus the inverse of a conformal map is holomorphic.

This is not an iff, take $f(z) = z^2$, then $2z \neq 0$ on $\mathbb{C} \setminus 0$ but \sqrt{z} has two values for every z , failing to be injective.

Proof .

Toward a contradiction, suppose $f'(z_0) = 0$ for some $z_0 \in U$. Then since f is holomorphic, we can expand about z_0 to obtain

$$f(z) - f(z_0) = a_k(z - z_0)^k + G(z), \quad a_k \neq 0, \quad k \geq 2$$

for all z near z_0 , where $G(z)$ vanishes to order $k + 1$ at z_0 .

For sufficiently small w , we write

$$f(z) - f(z_0) - w = F(z) + G(z) \quad \text{where} \quad F(z) = a_k(z - z_0)^k - w$$

Because $|G(z)| < |F(z)|$ on a small disc centered at z_0 and $G(z)$ vanishes to order $k + 1$ at z_0 (where $k > 1$), we can conclude that $F(z)$ has at least two distinct zeros inside this disc. Applying Rouché's theorem, we conclude that $f(z) - f(z_0) - w$ has at least two zeros as well. But this contradicts the injectivity of f .

Now let $g = f^{-1}$ on the range of f , which we can assume is V . For w close to w_0 , write $w = f(z)$ and $w_0 = f(z_0)$, yielding

????? See notes

■

Example 20.1 (Cayley Transform, Important).

The unit disc and upper half plane are mapped to each other via $F(z) = \frac{i - z}{i + z}$ with inverse

$$G(w) = i \frac{1 - w}{1 + w}.$$

Note that this is a fractional linear transformation.

Theorem 20.2(1.2).

The map $F : \mathbb{H} \rightarrow \mathbb{D}$ is a conformal map with inverse D .

Proof .

Both maps are holomorphic on their domains. Any point in \mathbb{H} is closer to i than $-i$, and we

want to show that $|F(z)| < 1$ for every $z \in \mathbb{H}$. We also need to show $\Re G(z) > 0$.

$$\begin{aligned} \operatorname{Im} G(w) &= \Re \left(\frac{1+u-iv}{1+u+iv} \right) \\ &= \dots \\ &= \frac{1-v^2-u^2}{(1+u)^2+v^2} \\ &> 0 \quad \text{if } u^2+v^2 < 1. \end{aligned}$$

This also shows that $u^2+v^2=1 \implies G(w)=0$. ■

Definition 20.2.1 (Fractional Linear Transform).

A function of the form $f(z) = \frac{az+b}{cz+d}$ where $ad-bc \neq 0$ is called a **fractional linear transformation**. The determinant condition here is to insure injectivity; otherwise this just yields the constant map. Note that $d = \frac{bc}{a}$

Example 20.2.

$\operatorname{GL}(2, \mathbb{C}), \operatorname{SL}(2, \mathbb{C})$, etc

Fact Fractional linear transformations are determined by their values on $0, 1, \infty$. Thus they form a group $\operatorname{SL}(2, \mathbb{C}) / \{\pm 1\} = \operatorname{PSL}(2, \mathbb{C})$.

We can define \mathbb{PC}^1 by taking $(u, v) \in \mathbb{C}^2 \setminus 0$ and setting $u \sim v$ iff $u = \lambda v$ for $\lambda \neq 0$. In this case, FLTs are linear maps $\mathbb{PC}^1 \circlearrowleft$ where we send $f(z)$ to $[a, b; c, d] \cdot [z, 1]$. Note that $\frac{f(-d)}{c} = \infty = [1, 0]$.

The four basic types of FLT are

- Translation: $T(z) = z + b$
- Rotation: $T(z) = e^{i\theta} z$
- Dilation $T(z) = az$ for $a > 0$.
- Inversion $T(z) = \frac{1}{z}$.

In the special case that $c = 0$, we have $T(z) = \frac{a}{d}z + \frac{b}{d}$ which is a rotation followed by a translation. If $c = 0$, ???

Proposition 20.3.

LFTs form a group under function composition.

Proof.

Just need to check that $w^{-1} = \frac{aw-b}{-cw+a}$. ■

Theorem 20.4.

If f is holomorphic on $\mathbb{C} \setminus \{z_0\}$ and injective, then f is an FLT.

Proof.

Up to a translation, we can assume that $z_0 = 0$. Then f has a Laurent series expansion

$$f(z) = \sum_{n=-\infty}^{\infty} a_n z^n.$$

If f has an essential singularity at zero, then by Casorati-Weierstrass implies that the image of over punctured disc is dense in \mathbb{C} . In particular, $B := \left\{ z \mid |z - 1| < \frac{1}{2} \right\}$ and there exists a $\zeta \notin B$ such that $f(\zeta) \in f(B)$. But then there exists a $z \in B$ such that $f(z) = f(\zeta)$, contradicting injectivity of f .

If f has a pole, it must be order at most 1, otherwise the reciprocal will have a zero of order 2 and fail injectivity, and f is injective iff $1/f$ is injective. Then the Laurent series has at most 3 terms, $az^{-1} + b + cz$. But $a = 0$, otherwise solving by the quadratic formula yields two roots. ■

21 Wednesday April 1st

We call $f : U \rightarrow V$ biholomorphic if it admits a bijective holomorphic inverse.

Proposition 21.1.

If $f : U \rightarrow V$ is holomorphic and injective, then $f'(z) \neq 0$, f is biholomorphic onto its image, and thus the inverse of a conformal map is also holomorphic.

Proof.

We argue by contradiction and suppose $f'(z_0) = 0$ for some $z_0 \in U$. Then $f(z) - f(z_0) = a(z - z_0)^k + G(z)$ for all z near z_0 , with $a \neq 0, k \geq 2$, and G vanishing to order $k + 1$ at z_0 . For w small enough, we write $f(z) - f(z_0) - w = F(z) + G(z)$ where $F(z) = a(z - z_0)^k - w$.

Since $|G| < |F|$ on the boundary of a small disc $D_\varepsilon(z_0)$ and F has at least two zeros in $D_\varepsilon(z_0)$, Rouché's theorem implies that $f(z) - f(z_0) - w$ has at least two zeros in this disc.

Since $f'(z) \neq 0$ for all z in a small punctured neighborhood of z_0 , it follows that that roots of $f(z) - f(z_0) - w$ are distinct. But then f is not injective, a contradiction.

Now let $g = f^{-1}$ be the inverse of f on its range, which we can assume is V . The second part of the proof follows from a Calculus argument, see slides. ■

Definition 21.1.1.

Two open sets are *conformally equivalent* iff there exist biholomorphic functions composing to the identity.

Recall the Cayley transform $w = F(z) = \frac{i-z}{i+z}$ with inverse $z = G(w) = i\frac{1-w}{1+w}$.

Theorem 21.2.

The map $F : \mathbb{H} \rightarrow \mathbb{D}$ is a conformal map with inverse G .

Proof (Sketch).

Use the fact that any point in \mathbb{H} is closer to i than $-i$, so $|F| < 1$. Then show $\Im G(w) > 0$ by expanding $w = u + iv$ and using that fact that $u^2 + v^2 < 1$. ■

The Cayley transform is a special case of a FLT $f(z) = \frac{az+b}{cz+d}$. Note that $f(-\frac{d}{c}) = \infty$ is a pole, so f should be defined with values in $\hat{\mathbb{C}} \cong \mathbb{CP}^1$. Since $\lim_{|z| \rightarrow \infty}$ exists, the domain is naturally $\hat{\mathbb{C}}$ as well.

Identify \mathbb{CP}^1 as the space of lines through 0 in \mathbb{C}^{n+1} . Explicitly, take $\mathbf{v}, \mathbf{w} \in (\mathbb{C}^{n+1})^\bullet$ and set $\mathbf{v} \sim \mathbf{w} \iff \mathbf{v} = \lambda \mathbf{w}$ for some $\lambda \in \mathbb{C}^\times$. Define open sets using the quotient topology, and this yields a metric defined by

$$d([u], [v]) = \left(\frac{q - |\langle u, v \rangle|}{\|u\| \cdot \|v\|} \right).$$

Let ∞ denote the point $(1, 0)^t \in \mathbb{CP}^1$, then every other point corresponds uniquely to an element of the form $(z, 1)^t$. For any $A \in \text{GL}(2, \mathbb{C})$, then A acts on such an element by $L_A(a) = (az+b, cz+d)^t = \frac{az+b}{cz+d} \in \mathbb{C}$ (by dividing through the second term).

Under function composition, these are Lie groups, and the map $A \mapsto L_A$ is a group morphism. For any $s \in \mathbb{C}$, $L_{sA} = L_A$, and $L_A = L_{A_1}$ for some matrix A_1 of determinant 1, so $A_1 \in \text{SL}(2, \mathbb{C})$. Finally, $L_{A_1} = L_{A_2} \iff A_2 = \pm A_1$, so the group of FLTs is given by $\text{PSL}(2, \mathbb{C}) = \text{SL}(2, \mathbb{C}) / \{\pm I\}$.

Now consider taking $a, b, c, d \in \mathbb{R}$, yielding the subgroup $\text{SL}(2, \mathbb{R})$. Then for any $A \in \text{GL}(2, \mathbb{R})$, we have $L_A = L_{A_1}$ iff $A_1 \in \text{SL}(2, \mathbb{R})$ and $\det A > 0$. Moreover, each such A preserves \mathbb{H} .

In particular,

$$\frac{az+b}{cz+d} = \frac{(az+b)(z\bar{z}+d)}{(cz+d)(c\bar{z}+d)} = \frac{R}{P} + iy \frac{ad-bc}{P}.$$

with

$$R = ac|z|^2 + bd + (ad+bc)x \in \mathbb{R}, P = |cz+d|^2 > 0, \quad \text{if } y > 0.$$

Thus $z \in \mathbb{H} \implies f(z) \in \mathbb{H}$, and $\text{Aut}_{\mathbb{C}}(\mathbb{H}) = \text{SL}(2, \mathbb{R})$. What is $\text{Aut}_{\mathbb{C}}(\mathbb{D})$?

We single out the transform $\phi(z) = \frac{z-i}{z+i}$ represented by $A_0 := \begin{bmatrix} 1 & -i & 1 & i \end{bmatrix}$. Conjugating the $\text{SL}(2, \mathbb{R})$ action on \mathbb{H} by ϕ yields a map $M_A : \mathbb{D} \rightarrow \mathbb{D}$.

Letting $A \in \mathrm{SL}(2, \mathbb{R})$ and computing $A_0 A A_0^{-1}$, we find that

$$A_0 \mathrm{SL}(2, \mathbb{R}) A_0^{-1} = \left\{ \begin{pmatrix} \alpha & \beta \\ \bar{\beta} & \bar{\alpha} \end{pmatrix} \in \mathrm{GL}(2, \mathbb{C}) : |\alpha|^2 - |\beta|^2 = 1 \right\} = \mathrm{SU}(1, 1).$$

It turns out that this is $\mathrm{Aut}_{\mathbb{C}}(\mathbb{D})$. It can be checked directly that for any matrix B in this group, it in fact send $\partial\mathbb{D} \rightarrow \partial\mathbb{D}$ by computing the modulus.

Recall that there are four basic types of FLT:

- Translation
- Rotation
- Dilation
- Inversion

Moreover, any FLT can be decomposed as a composition of these 4 types:

- If $c = 0$, then $T(z) = \frac{a}{d}z + \frac{b}{d}$ which is a dilation, a rotation, then a translation
- If $c \neq 0$, then long division yields $T(z) = \frac{bc - ad}{c^2} \cdot \frac{1}{z + \frac{d}{c}} + \frac{a}{c}$.

Theorem 21.3.

If f is holomorphic on $\mathbb{C} \setminus \{z_0\}$ and injective, then f is a FLT.

Proof.

Up to translation, assume $z_0 = 0$. Then f has a Laurent series expansion $f(z) = \sum_{n=-\infty}^{\infty} a_n z^n$.

Case 1: If f has an essential singularity at 0, then by Casorati-Weierstrauss, the image of every punctured neighborhood of 0 is dense in \mathbb{C} .

In particular, then if $B := \left\{ z \mid |z - 1| < \frac{1}{2} \right\}$, there exists a $\zeta \notin B$ with $f(\zeta) \in f(B)$. But then there is a $z \in B$ such that $f(z) = f(\zeta)$, contradicting injectivity.

Case 2: Suppose f has a pole of order n at 0, then $\frac{1}{f}$ has a zero of order n at 0. Since $\frac{1}{f}$ is injective, we must have $n \leq 1$ by a previous proposition showing that the derivative can not be zero.

Applying the same argument to $f(1/z)$ we conclude that $f(z) = \frac{a}{z} + b + cz$ for some constants $a, b, c \in \mathbb{C}$. If both $a \neq 0, c \neq 0$ then $cz^2 + (b - w)z + a = 0$ has two roots (up to multiplicity), contradicting injectivity.

So either $a = 0$ or $c = 0$, but not both since f is not constant. But in either case, f is an FLT. ■

Proposition 21.4.

Suppose f is holomorphic at z_0 . Then $f(z) - f(z_0) = \sum_{m=n}^{\infty} a_m(z - z_0)^m$ with $a_n \neq 0 \iff$ for ε small enough, there exists $\delta > 0$ such that $f(z) - w$ has distinct roots in $\{z \mid 0 < |z - z_0| < \varepsilon\}$ whenever $0 < |w - f(z_0)| < \delta$.

This states that $f(D_\varepsilon(z_0))$ covers $D_\delta(w_0) \setminus \{w_0\}$ exactly n times. In particular, f is injective in a neighborhood of $z_0 \iff f'(z_0) \neq 0$.

22 Friday April 3rd

22.1 Conformal Mappings

Qual Alert: basically everything today. E.g. Show that the conformal maps $\mathbb{C} \rightarrow \mathbb{C}$ are linear.

The three basic types are translation, dilations, and rotation.

For any $n \in \mathbb{N}$, the map $z \mapsto z^n$ is conformal in the sector $S = \{z \mid 0 < \arg(z) < \frac{\pi}{n}\}$. For $0 < \alpha < 2$, the map takes \mathbb{H} to $\{0 < \arg z < \alpha\pi\}$.

The map $z \mapsto \frac{1+z}{1-z}$ takes the upper half-disc \mathbb{D}^+ to the first quadrant \mathbb{H}^+ . The inverse is $\frac{w-1}{w+1}$ which is clearly holomorphic for $w \neq -1$, and its image is contained in the unit disc since the distance from w to -1 is always greater than the distance from w to 1 .

Note that

$$f(e^{i\theta}) = \frac{1+e^{i\theta}}{1-e^{i\theta}} = \frac{e^{-i\theta/2} + e^{i\theta/2}}{e^{-i\theta/2} - e^{i\theta/2}} = \frac{2\cos\frac{\theta}{2}}{-2i\sin\frac{\theta}{2}} = i\cot\frac{\theta}{2}$$

and thus as θ travels from 0 to π along S^1 , $f(e^{i\theta})$ travels from $i\infty$ to 0 .

The logarithm $z \mapsto \log z$ (taking the branch cut along the negative imaginary axis) maps \mathbb{H} to the strip $\{z \mid x \in \mathbb{R}, 0 < y < \pi\}$. The inverse is given by $w \mapsto e^w$, and as x travels from $-\infty$ to 0 , $f(x)$ travels from $\infty + i\pi$ to $-\infty + i\pi$. When x travels from $0 \rightarrow \infty$, $f(x)$ travels from $-\infty_{\mathbb{R}} \rightarrow \infty_{\mathbb{R}}$.

The map $z \mapsto \log z$ also defined as map from the half disc \mathbb{D}^+ to the half-strip $\mathbb{S} = \{x < 0, 0 < y < \pi\}$. We have $[1, -1]_{\mathbb{R}} \mapsto [-\infty, 0]$ and $S_+^1 \mapsto i[0, \pi]$.

The map $z \mapsto -\frac{1}{2}\left(z + \frac{1}{z}\right)$ takes $\mathbb{D}^+ \rightarrow \mathbb{H}$. We have $[0, 1] \mapsto [1, \infty]$ and $S_+^1 \mapsto [-1, 1] \subset \mathbb{R}$, and $[0, -1] \mapsto [-1, -\infty] \subset \mathbb{R}$.

The map $z \mapsto \sin z$ takes $\{-\pi/2 < x < \pi/2, y > 0\}$ onto \mathbb{H} . Then $[-\pi/2 + i\infty, -\pi/2 + 0] \mapsto [-\infty, 1]$ and $[-\pi/2, \pi/2] \mapsto [-1, 1]$, and $[\pi/2 + 0i, \pi/2 + o\infty] \mapsto [1, \infty]$.

Just need to know these 8 examples of conformal mappings.

23 Monday April 6th

Things to know well:

- Cauchy Integral Formula
- Estimates for derivatives, mean value theorem
- Rouché's theorem
- Casorati-Weierstrass

23.1 Automorphisms of the Disc

Lemma 23.1 (Schwarz).

Let $f : \mathbb{D} \rightarrow \mathbb{D}$ be holomorphic with $f(0) = 0$, then

1. $|f(z)| \leq |z|$ for all $z \in \mathbb{D}$.
2. If for some $z_0 \neq 0$ we have $|f(z_0)| = |z_0|$, then f is a rotation (i.e. $f(z) = e^{i\theta}z$)
3. $|f'(0)| \leq 1$ and if equality holds, f is a rotation.

Proof.

1. Expand $f(z) = a_1z + a_2z^2 + \dots$ using $f(0) = 0 \implies a_0 = 0$. Then $f(z)/z$ is holomorphic in \mathbb{D} and bounded in modulus by $1/r$ for $r = |z| < 1$. By the maximum modulus principle, this is true for any $|z| < r$, so letting $r \rightarrow 1$ yields (1).
2. Since $|f(z)| < 1$, the modulus of $f(z)/z$ attains its maximum in \mathbb{D}° and thus is constant. So $f(z) = cz$ and at z_0 we have $|f(z)/(z-0)| = 1$, so $|c| = 1$ and $f(z)$ is a rotation.
3. If $g(z) = f(z)/z$ then $|g(z)| < 1$ for all $z \in \mathbb{D}$ and $g(0) = \lim_{z \rightarrow 0} \frac{f(z)f'(0)}{z} = f'(0)$. If $|f'(0)| = 1$ then $|g(0)| = 1$, ???.

■

We proved that $\text{Aut}\mathbb{D} = \text{SU}(1, 1)$, which preserves a certain Hermitian form and is a non-compact group. We also showed that $\text{Aut}\mathbb{H} = \text{SL}(2, \mathbb{R})$.

Note that the rotations $r_\theta : z \mapsto e^{i\theta}z \in \text{Aut}\mathbb{D}$. There are also functions of the form $\psi_\alpha : z \mapsto \frac{\alpha - z}{1 - \bar{\alpha}z}$ where $\alpha \in \mathbb{D}$. It is holomorphic in \mathbb{D} with a simple pole at $z = 1/\bar{\alpha}$.

Writing $z = e^{i\theta}$ yields

$$\psi_\alpha(e^{i\theta}) = \frac{\alpha - e^{i\theta}}{1 - \bar{\alpha}e^{i\theta}} = -e^{-i\theta} \frac{\alpha - e^{i\theta}}{\bar{\alpha} - e^{-i\theta}} \implies |\psi_\alpha(e^{i\theta})| = 1.$$

By the MMP, $|\psi_\alpha(z)| < 1$ for all $z \in \mathbb{D}$. The inverse can be solved for, and it turns out that $\psi_\alpha^{-1} = \psi_\alpha$ where $0 \rightleftharpoons \alpha$.

Theorem 23.2.

$$\text{Aut}(\mathbb{D}) = \left\{ f(z) = e^{i\theta} \frac{\alpha - z}{1 - \bar{\alpha}z} : \theta \in \mathbb{R}, |\alpha| < 1 \right\}.$$

Note that this group is not compact, since it's homeomorphic to $\mathbb{R} \times \mathbb{D}$.

Proof.

Given $f \in \text{Aut}(\mathbb{D})$, there must be some α such that $f(\alpha) = 0$. Consider $g = f \circ \psi_\alpha$, then $g(0) = 0$ and applying the Schwarz lemma yields $|g(z)| \leq |z|$ for all $z \in \mathbb{D}$. Since $g^{-1}(0) = 0$, applying this lemma again to g^{-1} shows $|g^{-1}(w)| \leq |w|$ for all $w \in \mathbb{D}$. Letting $w = g(z)$ we obtain $|g(z)| = |z|$ for all $z \in \mathbb{D}$, so by Schwarz $g(z) = e^{i\theta}z$ is a rotation. Thus $f(z) = e^{i\theta}\psi_\alpha(z)$. ■

Recall that $F(z) = \frac{i-z}{i+z} : \mathbb{H} \rightarrow \mathbb{D}$ has inverse $i\frac{1-w}{1+w}$, so we can define a map $\Gamma : \text{Aut}(\mathbb{D}) \rightarrow \text{Aut}(\mathbb{H})$ where $\phi \mapsto F^{-1}\phi F$. This can be shown directly using algebra

24 Appendix

$$dz = dx + i dy$$

$$d\bar{z} = dx - i dy$$

$$f_z = f_x = i^{-1}f_y$$

$$\int_0^{2\pi} e^{i\ell x} dx = \begin{cases} 2\pi & (\ell = 0) \\ 0 & (\ell \neq 0) \end{cases}.$$

- Holomorphic: once complex differentiable in neighborhoods of every point.
- Analytic: equal to its Taylor series expansion

Collection of facts used on problem sets

Standard forms of conic sections:

- Circle: $x^2 + y^2 = r^2$
- Ellipse: $\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 = 1$
- Hyperbola: $\left(\frac{x}{a}\right)^2 - \left(\frac{y}{b}\right)^2 = 1$
 - Rectangular Hyperbola: $xy = \frac{c^2}{2}$.
- Parabola: $-4ax + y^2 = 0$.

Mnemonic: Write $f(x, y) = Ax^2 + Bxy + Cy^2 + \dots$, then consider the discriminant $\Delta = B^2 - 4AC$:

- $\Delta < 0 \iff$ ellipse
 - $\Delta < 0$ and $A = C, B = 0 \iff$ circle
- $\Delta = 0 \iff$ parabola
- $\Delta > 0 \iff$ hyperbola

Completing the square:

$$x^2 - bx = (x - s)^2 - s^2 \quad \text{where } s = \frac{b}{2}$$

$$x^2 + bx = (x + s)^2 - s^2 \quad \text{where } s = \frac{b}{2}.$$

Useful Properties

- $\Re(z) = \frac{1}{2}(z + \bar{z})$ and $\Im(z) = \frac{1}{2i}(z - \bar{z})$.
- $z\bar{z} = |z|^2$
- $\cos(\theta) = \frac{1}{2}(e^{i\theta} + e^{-i\theta})$
- $\sin(\theta) = \frac{1}{2i}(e^{i\theta} - e^{-i\theta})$.

Useful Series

$$\sum_{k=1}^n k = \frac{n(n+1)}{2}$$

$$\sum_{k=1}^n k^2 = \frac{n(n+1)(2n+1)}{6}$$

$$\sum_{k=1}^n k^3 = \frac{n^2(n+1)^2}{4}$$

$$\log(z) = \sum_{j=0}^{\infty} (-1)^j \frac{(z-a)^j}{j}$$

Cauchy-Riemann Equations

$$u_x = v_y \quad \text{and} \quad u_y = -v_x$$

$$\frac{\partial u}{\partial r} = \frac{1}{r} \frac{\partial v}{\partial \theta} \quad \text{and} \quad \frac{\partial v}{\partial r} = -\frac{1}{r} \frac{\partial u}{\partial \theta}$$

24.1 Useful Techniques

Showing a function is constant: Write $f = u + iv$ and use Cauchy-Riemann to show $u_x, u_y = 0$, etc.

Deriving Polar Cauchy-Riemann: See walkthrough here. Take derivative along two paths, along a ray with constant angle θ_0 and along a circular arc of constant radius r_0 . Then equate real and imaginary parts. See problem set 1.

Computing Arguments: $\text{Arg}(z/w) = \text{Arg}(z) - \text{Arg}(w)$.

The sum of the interior angles of an n -gon is $(n-2)\pi$, where each angle is $\frac{n-2}{n}\pi$.

24.2 Residues

If p is a simple pole, $\text{Res}(p, f) = \lim_{z \rightarrow p} (z - p)f(z)$. Example: Let $f(z) = \frac{1}{1 + z^2}$, then $\text{Res}(i, f) = \frac{1}{2i}$.

Green's Theorem: Todo

$$\frac{\partial}{\partial z} \sum_{j=0}^{\infty} a_j z^j = \sum_{j=0}^{\infty} a_{j+1} z^j.$$

24.3 Pithy Statements

- Little Picard: f misses at most one point and is a homeomorphism onto its image.
- Baire's Theorem: The intersection of open dense sets is open.
- Casorati-Weierstrass: The image of a disc punctured at an essential singularity is dense in \mathbb{C} .
- Open Mapping: Holomorphic functions preserve open sets.
- Argument Principle: The logarithmic derivative measures the difference of zeros and poles.
- Liouville: Bounded entire functions are constant.
- Maximum Modulus: Holomorphic functions take extrema only on boundaries.
- Cauchy Inequalities: The n th Taylor coefficient is at most $\sup_{|z|=R} |f|/R^n$.
- Cauchy's Theorem: Integrals of holomorphic functions vanish.
- Morera: Integrals vanishing along every rectangle implies holomorphic.
- Schwarz Reflection: ???
- Identity Theorem: Two functions agreeing on a set with a limit point are equal on a domain.
- The ring of holomorphic functions on a domain in \mathbb{C} has no zero divisors (by the identity principle).

24.4 Precise Refinements

Cauchy Inequality: Given $z_0 \in \Omega$, pick the largest disc $D_R(z_0) \subset \Omega$ and let $C_R = \partial D_R$. Using the integral formula, defining $\|f\|_{C_R} = \max_{|z-z_0|=R} |f(z)|$

$$|f^{(n)}(z_0)| \leq \frac{n!}{2\pi} \int_0^{2\pi} \frac{\|f\|_{C_R}}{R^{n+1}} R d\theta = \frac{n! \|f\|_{C_R}}{R^n}.$$
