### 1.1 Schur Algebras

Let  $G = \mathrm{GL}(n, k)$ , then polynomial representations of  $G$  are equivalent to  $S(n, d)$  modules for all  $d \geq 0$ , where we can note that  $S(n, d) = \mathrm{End}_{\Sigma_d}(V^{\otimes d})$ . We'll have a correspondence

$$\{L(\lambda) \text{ simple modules for } S(n, d)\} \iff \Lambda^+(n, d), \text{ partitions of } d \text{ with at most } n \text{ parts,}$$

#### Example 1.1.1.

Good example, can see all filtrations at work, tilting modules, etc.

Consider  $S(3, 3)$  for  $p = 3$ , we then have the partitions  $\Lambda^+(3, 3) = \{(3), (2, 1), (1, 1, 1)\}$ . We can think of these in the  $\varepsilon$  basis as  $(3) = (3, 0, 0), (2, 1) = (2, 1, 0)$ . Since  $\mathrm{SL}(3, k) \subset \mathrm{GL}(3, k)$ , we can find the  $SL(3, k)$  weights by taking successive differences to yield  $(3, 0), (1, 1), (0, 0)$  with the corresponding picture

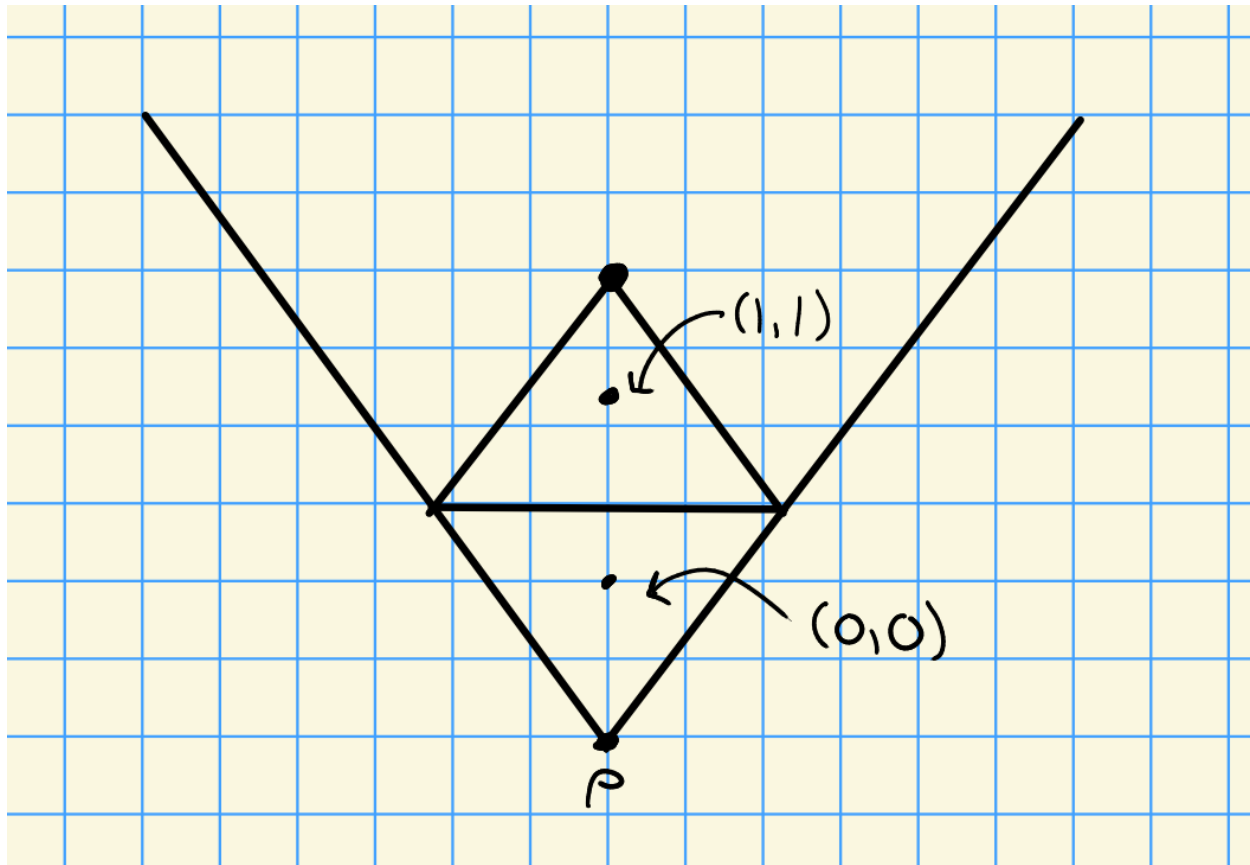

Figure 1: Image

We can compute

- $L(1, 1, 1) = H^0(1, 1, 1)$
- $L(2, 1) = H^0(2, 1)$
- $L(3) = H^0(3)$

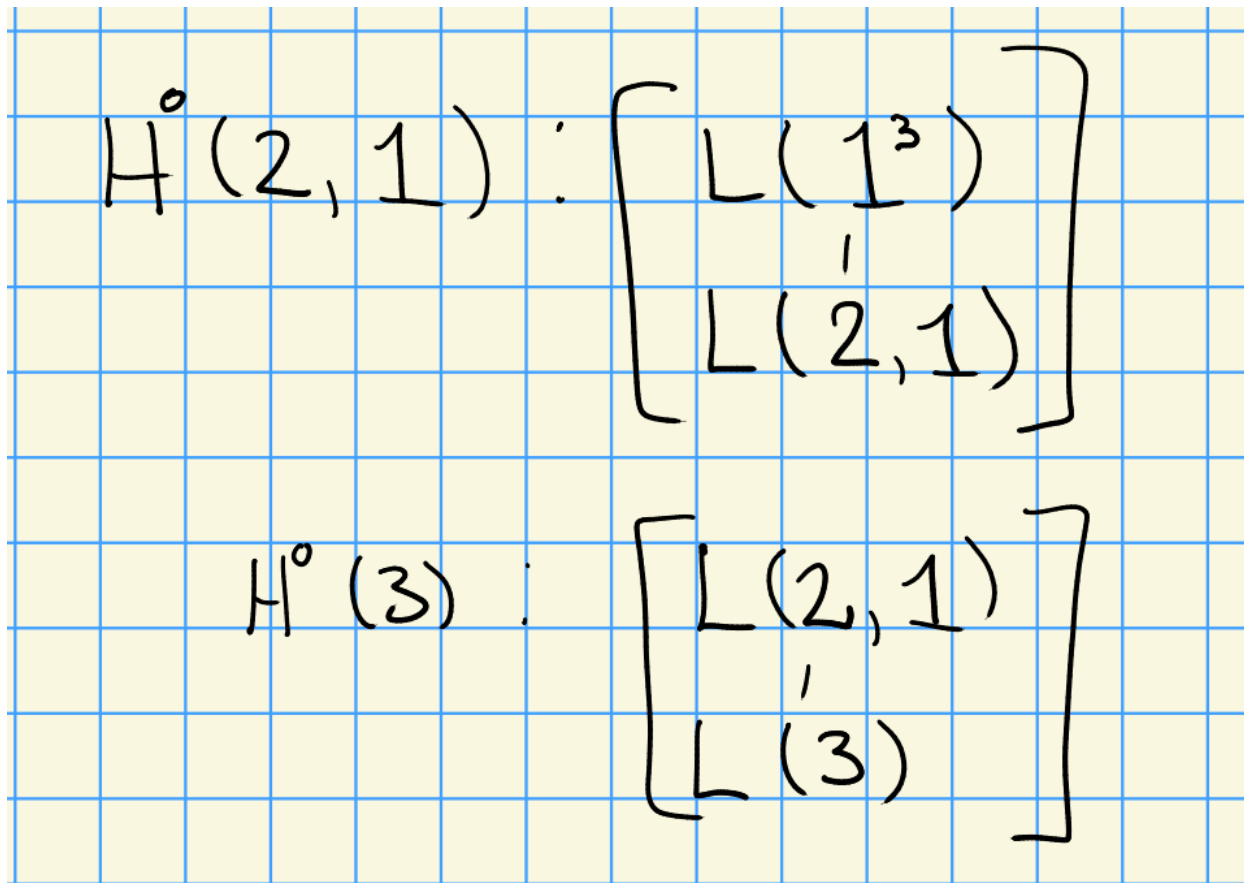

$$H^0(2, 1) : \left[ \begin{array}{c} L(1^3) \\ L(2, 1) \end{array} \right]$$
$$H^0(3) : \left[ \begin{array}{c} L(2, 1) \\ L(3) \end{array} \right]$$

Figure 2: Image

We have a form of Brauer reciprocity:

$$[I(\lambda) : H^0(\mu)] = [H^0(\mu) : L(\lambda)].$$

We can now compute the injective hulls:

$$\begin{aligned}
 I(3) &: \begin{bmatrix} L(2,1) \\ L(3) \end{bmatrix} \\
 I(2,1) &: \begin{bmatrix} L(2,1) \\ L(3) \quad L(1^3) \\ L(2,1) \end{bmatrix} \\
 I(1^3) &: \begin{bmatrix} L(1^3) \\ L(2,1) \\ L(3) \end{bmatrix} \text{ (uniserial)}
 \end{aligned}$$

Figure 3: Image

What are the tilting modules? We can use the fact that  $L(1^3) = V(1^3)$ . It has a good filtration and a Weyl filtration and thus must be the tilting module for  $L(1^3)$ .

Using the following fact:

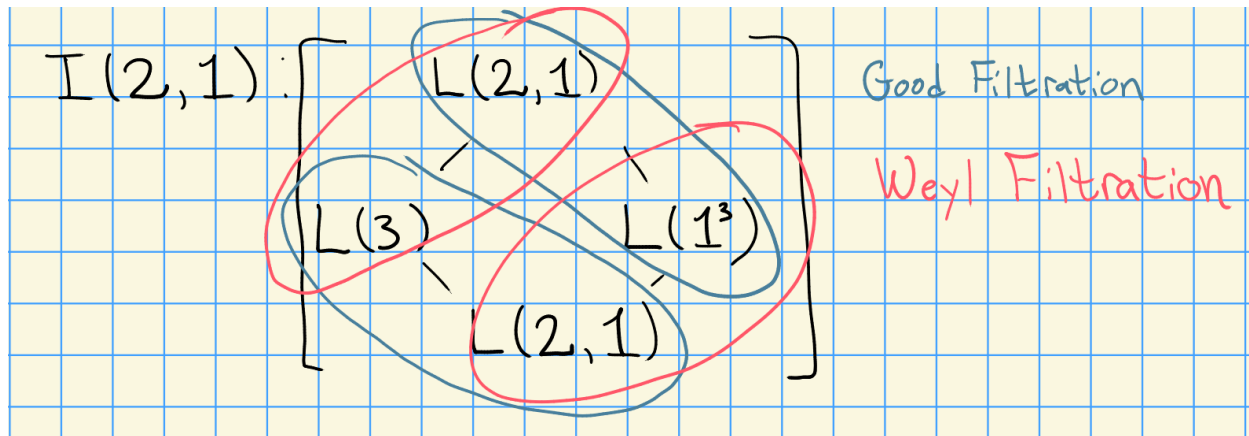

Figure 4: Image

We can compute the following:

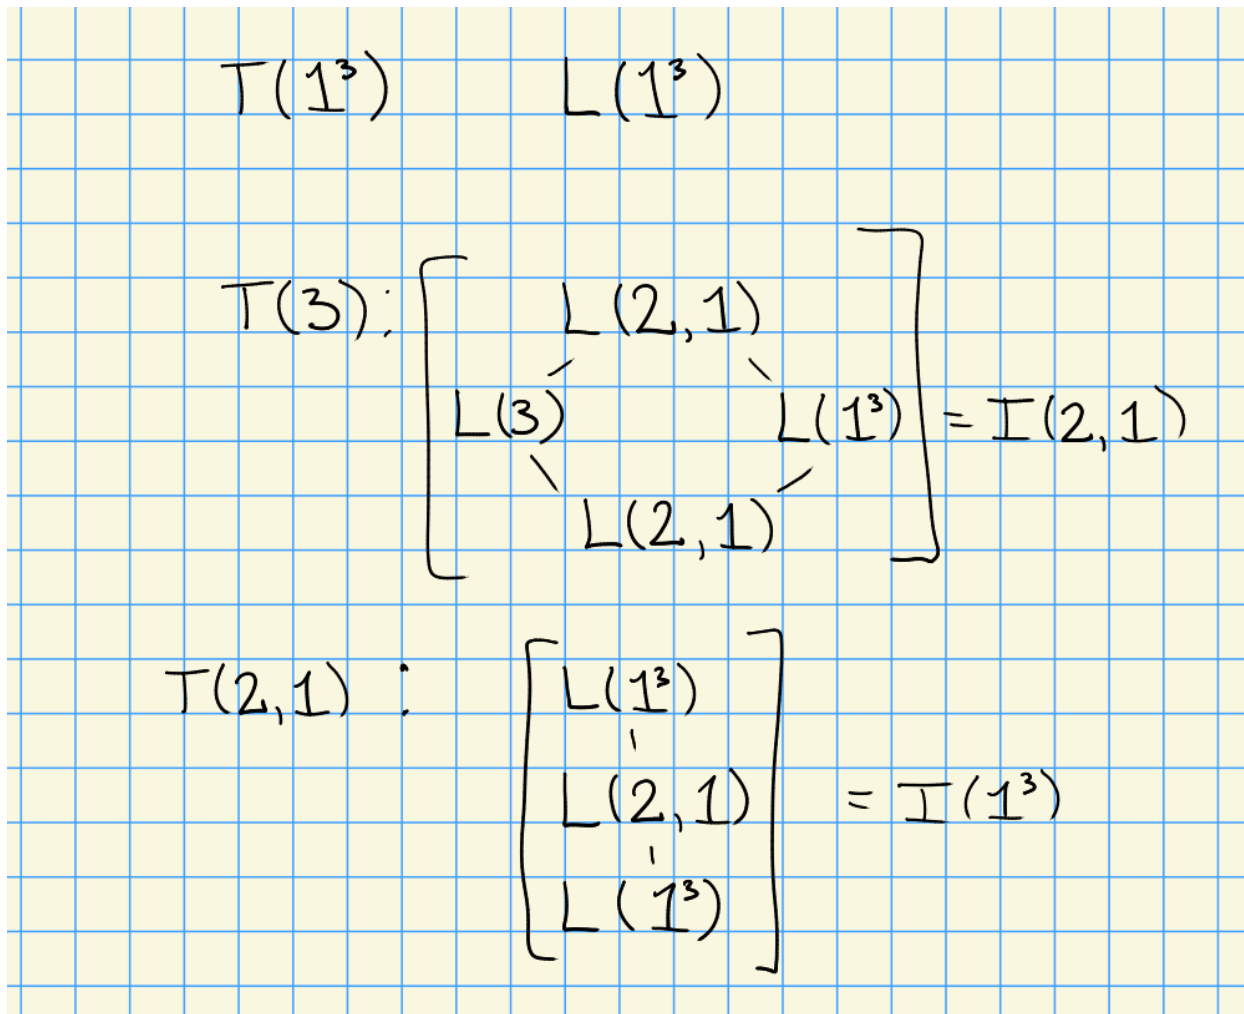

Figure 5: Image

## 1.2 Simplicity of $H^0(\lambda)$

1.  $k = \mathbb{C}$  implies  $L(\lambda) = H^0(\lambda)$  for all  $\lambda \in X(T)_+$
2.  $k = \bar{\mathbb{F}}_p$  implies  $L(\lambda) = H^0(\lambda)$  if  $\langle \lambda, \alpha_0^\vee \rangle \leq 1$  where  $\alpha_0$  is the highest short root.

Such  $\lambda$  are referred to as *minuscule weights*.

### Example 1.2.1.

For type  $A_n$ , we have  $\alpha_0 = \sum_{i=1}^n \alpha_i$ . For type  $G_2$ , we have  $\alpha_0^\vee = 2\alpha_1^\vee + 3\alpha_2^\vee$ .

### Example 1.2.2.

In type  $A_n$ , set  $\lambda = \sum_{j=1}^n c_j w_j$  where  $c_j \geq 0$ . Then  $\langle \lambda, \alpha_0^\vee \rangle = \sum c_j \leq 1$ , so  $\lambda$  is minuscule iff  $\lambda = 0$

or  $\lambda = w_j$  for some  $j$ .

**Remark 1.2.1.**

Quick timeline:

- 2015, Cantrell lectures by Dick Gross at UGA
- Fall 2015: email to Dan Nakano from Skip Garibaldi, conjecture from Gross without a proof

**Proposition 1.2.1 (Gross).**

The simple module is equal to the induced module, so  $L(\lambda) = H^0(\lambda)$ , for all  $\lambda$  iff  $\lambda$  is minuscule, or if  $L(\lambda) = \mathfrak{g}$  for  $\Phi = E_8$ .

- Proved by Garibaldi-Nakano-Guralnick, appeared in Journal of Algebra

### 1.3 Bott-Borel-Weil Theorem

We can consider the higher right-derived functors of  $\lambda$ , given by  $H^i(\lambda) = R^i \text{Ind}_B^G \lambda$  for  $\lambda \in X(T)$ . You can think of this as the higher sheaf cohomology of the flag variety,  $\mathcal{H}^i(G/B, \mathcal{L}(\lambda))$ .

We have **Kempf Vanishing**:  $H^i(\lambda) = 0$  for all  $i > 0$  when  $\lambda \in X(T)_+$  is dominant (although other things may happen for non-dominant weights). There is a correspondence  $(G, T) \iff (W, \Phi)$ , and since  $W$  is generated by simple reflections, we can write any  $w \in W$  as  $w = \prod s_{\alpha_i}$ . A *reduced expression* is one in which the length can not be shortened, and any two reduced expressions necessarily have the same length (number of simple reflections).

**Example 1.3.1.**

For  $\Phi = A_2$ , we have  $w_0 = s_{\alpha_1} s_{\alpha_2} s_{\alpha_1} = s_{\alpha_2} s_{\alpha_1} s_{\alpha_2}$ .
