1 Homework Problems

1.1 Problem 1

Todo

1.2 Problem 2

We can note that since f has 4 roots, the Galois group G of its splitting field will be a subgroup of S_4 . Moreover, G must be a *transitive subgroup* of S_4 , i.e. the action of G on the roots of f should be transitive. This reduces the possibilities to $G \cong S^4, A^4, D^4, \mathbb{Z}_4, \mathbb{Z}_2^2$.

Since f has exactly 2 real roots and thus a pair of roots that are complex conjugates, the automorphism given by complex conjugation is an element of G . But this corresponds to a 2-cycle $\tau = (ab)$, and we can then make the following conclusions:

- Not A_4 : A_4 contains only even cycles, and τ is odd.
- Not \mathbb{Z}_4 : This subgroup is generated by a single 4-cycle σ , which up to conjugacy is (1234) , and σ^n is not a 2-cycle for any n .

- Not \mathbb{Z}_2^2 : In order to be transitive, this subgroup must be $\{e, (12)(34), (13)(24), (14)(23)\}$, which does not contain τ .

The only remaining possibilities are S^4 and D^4 . \square

1.3 Problem 3

1.3.1 Part 1

To see that $\phi(n)$ is even for all $n > 2$, we can take a prime factorization of n and write

$$\phi(n) = \phi\left(\prod_{i=1}^m p_i^{k_i}\right) = \prod_{i=1}^m \phi(p_i^{k_i}) = \prod_{i=1}^m p_i^{k_i-1}(p_i - 1) = \prod_{i=1}^m p_i^{k_i-1} \prod_{i=1}^m (p_i - 1)$$

where each $k_i \geq 1 \implies k_i - 1 \geq 0$. But every prime power is odd, and a product of odd numbers is odd, so the first product is odd. It is also true that $p - 1$ is even for every prime p , and the second term is a product of even terms and thus even. So $\phi(n)$ is the product of an even and an odd number, which is always even.

1.3.2 Part 2

Suppose $\phi(n) = 2$. Take a prime factorization of n , so we have

$$2 = \phi(n) = \prod_{i=1}^m \phi(p_i^{k_i})$$

Since the only factors of 2 are 1 and 2, we must have $\phi(p_i^{k_i}) = 2$ for exactly one i .
