Prerequisites:

- Homological Algebra
  - Abelian Categories
  - Derived Functors
  - Spectral Sequences (just exposure!)
- Sheaf theory and sheaf cohomology
- Schemes (Hartshorne II and III)

Outline/Goals:

- Basics of etale cohomology
    - Etale morphism
    - Grothendieck topologies
    - The etale topology
    - Etale cohomology and the basis theorems
    - Etale cohomology of curves
    - Comparison theorems to singular cohomology
    - Focused on the case where coefficients are a constructible sheaf.
  - Prove the Weil Conjectures (more than one proof)
    - Proving the Riemann Hypothesis for varieties over finite fields
- One of the greatest pieces of 20th century mathematics!
- Topics
    - Weil 2 (Strengthening of RH, used in practice)
    - Formality of algebraic varieties (topological features unique to varieties)
    - Other things (monodromy, refer to Katz' AWS notes)

What is Etale Cohomology? Suppose  $X/\mathbb{C}$  is a quasiprojective variety: a finite type separated integral  $\mathbb{C}$ -scheme.

---

If you take the complex points, it naturally has the structure of a complex analytic space  $X(\mathbb{C})^{\text{an}}$ : you can give it the Euclidean topology, which is much finer than the Zariski topology.

For a nice topological space, we can associate the singular cohomology  $H^i(X(\mathbb{C})^{\text{an}}, \mathbb{Z})$ , which satisfies several nice properties:

- Finitely generated  $\mathbb{Z}$ -modules
- Extra Hodge structure when tensored up to  $\mathbb{C}$  (same as  $\mathbb{C}$  coefficients)
- Cycle classes (i.e. associate to a subvariety a class in cohomology)

Goal of etale cohomology: do something similar for much more general “nice” schemes. Note that some of these properties are special to complex varieties

E.g. finitely generated: not true for a random topological space

We’ll associate  $X$  a “nice scheme”  $\rightsquigarrow H^i(X_{\text{et}}, \mathbb{Z}/\ell^n \mathbb{Z})$ . Take the inverse limit over all  $n$  to obtain the  $\ell$ -adic cohomology  $H^i(X_{\text{et}}, \mathbb{Z}_\ell)$ . You can tensor with  $\mathbb{Q}$  to get something with  $\mathbb{Q}_\ell$  coefficients. And as in singular cohomology, you can a “twisted coefficient system”.

What are nice schemes:

- $X = \text{Spec } \mathcal{O}_k$ , the ring of integers over a number field.
- $X$  a variety over an algebraically closed field
  - Typical, most analogous to taking a variety over  $\mathbb{C}$ .
- $X$  a variety over a non-algebraically closed field

Some comparisons between the last two cases:

- For  $\mathbb{C}$ - variety,  $H_{\text{sing}}^i$  will vanish above  $i = 2d$ .
- Over a finite field,  $H^i$  will vanish for  $i > 2d + 1$  but generally not vanish for  $i = 2d + 1$ .

In good situations, these are finitely generated  $\mathbb{Z}/\ell^n \mathbb{Z}$ -modules, have Mayer-Vietoris and excision sequences, spectral sequences, etc.

Related invariants: for a scheme with a geometric point  $(X, \bar{x}) \rightsquigarrow \pi_1^{\text{étale}}(X, \bar{x})$ , which is a profinite topological group, which is a profinite topological group.

Note: a geometric point is a map from  $\text{Spec } X$  to an algebraically closed field.

More invariants beyond the scope of this course:

- Higher homotopy groups
- Homotopy type (equivalence class of spaces)

So we want homotopy-theoretic invariants for varieties.

### Remark 1.

This cohomology theory is necessarily weird!

#### Theorem 1.1 (Serre).

There does not exist a cohomology theory for schemes over  $\bar{\mathbb{F}}_q$  with the following properties:

1. Functorial
2. Satisfies the Kunneth formula
3. For  $E$  an elliptic curve,  $H^1(E) = \mathbb{Q}^2$ .

Slogan: No cohomology theory with  $\mathbb{Q}$  coefficients.

---

*Proof .*

Take  $E$  to be a supersingular elliptic curve. Then  $\text{End}(E) \otimes \mathbb{Q}$  is a quaternion algebra.

Fact: There are no algebra morphisms  $R \rightarrow \text{Mat}_{2 \times 2}(\mathbb{Q})$

**Exercise .**

Functoriality and Kunneth implies that  $\text{End}(E) \curvearrowright E$  yields an action on  $H^1(E)$ , which is precisely an algebra morphism  $\text{End}(E) \rightarrow \text{Mat}_{2 \times 2}(\mathbb{Q})$ , a contradiction.

The content: the sum of two endomorphisms act via their sum on  $H^1$ .

**Exercise .**

Prove the same thing for  $\mathbb{Q}_p$  coefficients, where  $p$  divides the characteristic of the ground field.

Proof the same, just need to know what quaternion algebras show up.

■

This forces using some funky type of coefficients.

What are the Weil Conjectures?

Suppose  $X/\mathbb{F}_q$  is a variety, then

$$\zeta_X(t) = \exp \left( \sum_{n>0} \frac{|X(\mathbb{F}_{q^n})|}{n} t^n \right).$$

Some comments:

- $\frac{\partial}{\partial t} \log \zeta_X(t)$  is an ordinary generating function for the number of rational points.
- Slogan: locations of zeros and poles of a meromorphic function control the growth rate of the coefficients of the Taylor series of the logarithmic derivative.

**Exercise 1.3.**

Make this slogan precise for rational functions, i.e. ratios of two polynomials.

The conjectures:

1.  $\zeta_X(t)$  is a rational function.
2. (Functional equation) For  $X$  smooth and proper

$$\zeta_X(q^{-n}t^{-1}) = \pm q^{\frac{nE}{2}} t^E \zeta_X(t).$$

3. (RH) All roots and poles of  $\zeta_X(t)$  have absolute value  $q^{\frac{i}{2}}$  with  $i \in \mathbb{Z}$ , and these are equal to the  $i$ th Betti numbers if  $X$  lifts to characteristic zero.

Note: we'll generalize betti numbers so this makes sense in general.

All theorems! Proofs:

- 
1. Dwork, using  $p$ -adic methods. Proof here will follow from the fact that  $H_{\text{étale}}^i$  are finite-dimensional. Related to Lefschetz Trace Formula (how Grothendieck thought about it).
  2. Grothendieck, follows from some version of Poincaré duality.
  3. (and 4) Deligne.

Euler Product:

Let  $|X|$  denote the closed points of  $X$ , then

$$\zeta_X(q^{-n}t^{-1}) = \pm q^{\frac{nE}{2}} t^E \zeta_X(t) = \prod_{x \in |X|} \exp \left( t^{\deg(x)} + \frac{t^{2 \deg(x)}}{2} + \cdots \right).$$

*Proof.*

If you have a point of  $\deg(x) = n$ , how many  $\mathbb{F}_{q^n}$  points does this contribute? I.e., how many maps are there  $\text{Spec}(\mathbb{F}_{q^n}) \rightarrow \text{Spec}(\mathbb{F}_{q^n})$  over  $\mathbb{F}_q$ ?

There are exactly  $n$ ,

■
