1.1 Problem 1

Note that if either $p = 1$ or $q = 1$, G is a p-group, which is a nontrivial center that is always normal. So assume $p \neq 1$ and $q \neq 1$.

We want to show that G has a non-trivial normal subgroup. Noting that $\#G = p^2 q$, we will proceed by showing that either n_p or n_q must be 1.

We immediately note that

$$\begin{aligned} n_p &\equiv 1 \mod p \\ n_p &\mid q \end{aligned} \qquad\qquad \begin{aligned} n_q &\equiv 1 \mod q \\ n_q &\mid p^2, \end{aligned}$$

which forces

$$n_p \in \{1, q\}, \quad n_1 \in \left\{1, p, p^2\right\}.$$

If either $n_p = 1$ or $n_q = 1$, we are done, so suppose $n_p \neq 1$ and $n_1 \neq 1$. This forces $n_p = q$, and we proceed by cases:

1.1.1 Case 1: $p = q$.

Then $\#G = p^3$ and G is a p-group. But every p-group has a non-trivial center $Z(G) \leq G$, and the center is always a normal subgroup.

1.1.2 Case 2: $p > q$.

Since $n_p \neq 1$ by assumption, we must have $n_p = q$. Now consider sub-cases for n_q:

- $n_q = p$: If $n_q = p = 1 \mod q$ and $p < q$, this forces $p = 1$.
- $n_q = p^2$: We will reach a contradiction by showing that this forces

$$\left| P := \bigcup_{S_p \in \mathrm{Syl}(p,G)} S_p \setminus \{e\} \right| + \left| Q := \bigcup_{S_q \in \mathrm{Syl}(q,G)} S_q \setminus \{e\} \right| + |\{e\}| > |G|.$$

  Towards this end, consider the contribution of Q, which is exactly

$$n_q(q-1) = p^2(q-1) = p^2 q - p^2$$

  elements. Every such element is of order q, so this leaves

$$|G| - |Q| = p^2 q - (p^2 q - p^2) = p^2$$

  elements of order **not** equal to q.

  The remaining nontrivial elements can only be of order p or p^2. We thus have

$$\begin{aligned} |P| + |Q| + |\{e\}| &= n_p(q-1) + n_q(p^2-1) + 1 \\ &= p^2(q-1) + q(p^2-1) + 1 \\ &= p^2(q-1) + 1(p^2-1) + (q-1)(p^2-1). \end{aligned}$$
