Problem 1.0.1 (Prove Corollary 2.3.2)

For R a PID, show that an R-module A is divisible if and only if A is injective.

Recall that a module is divisible if and only if for every $r \neq 0 \in R$ and every $a \in A$, we have a = br for some $b \in A$.

Solution:

Note: we'll assume R is commutative, and since R is a domain, it has no nonzero zero divisors and thus all elements $r \in R$ are left-cancelable.

 \implies : Suppose A is divisible, we then want to show every R-module morphism of the following form lifts, where we regard the ideal J and the ring R as R-modules:

Link to Diagram

Since R is a PID, we have J = jR for some $j \in \overline{R}$, so it suffices to produce lifts of the following form:

Link to Diagram

Consider $f(j) \in A$. Since A is divisible, we have A = jA, so we can write $f(j) = j\mathbf{a}'$ for some $\mathbf{a}' \in A$. Using R-linearity and the fact that j is left-cancelable, we have

$$jf(1_R) = f(j) = j\mathbf{a}' \implies f(1_R) = \mathbf{a}'.$$

Thus we can set

$$\tilde{f}: R \to A$$

$$1_R \mapsto \mathbf{a}'.$$

and extending R-linearly yields a well-defined R-module morphism. Moreover, the diagram commutes by construction, since $\iota(1_R) = 1_R$.

 \Leftarrow : Suppose $A \in R$ -Mod is injective, where by Baer's criterion we equivalently have a lift of the following form for every $J \subseteq R$:

Link to Diagram

Let $j \in R$ be a nonzero element that is not a zero-divisor, we then want to show that A = jA, i.e. that for every $\mathbf{a} \in A$, there is a $\mathbf{a}' \in A$ such that $\mathbf{a} = j\mathbf{a}'$. Fixing $\mathbf{a} \in A$, define a map $f_a : J \to A$ in the following way: for $x \in J$, use the fact that $\langle j \rangle \coloneqq jR$ to first write x = jr for some $r \in R$, and then set $f_a(x) = f_a(jr) \coloneqq r\mathbf{a}$. To summarize, we have

$$f_a: J = jR \to R$$

 $x = jr \mapsto r\mathbf{a}.$

By injectivity, we can take the inclusion $jR \hookrightarrow R$ and get a lift:

Link to Diagram

We can now use the fact that

$$r\mathbf{a} = f_a(jr)$$

$$= \tilde{f}_a(\iota(jr))$$

$$= \tilde{f}_a(jr)$$

$$= jr\tilde{f}_a(1_R) \qquad \text{using R-linearity and $j,r \in R$}$$

$$= rj\tilde{f}_a(1_R) \qquad \text{since R is commutative}$$

$$\implies \mathbf{a} = j\tilde{f}_a(1_R) \in jA,$$

where in the last step we have canceled an r on the left. So in the definition of divisibility, we can take

$$\mathbf{a}' \coloneqq \tilde{f}_a(1_R),$$

and letting a range over all elements of A yields the desired result.

Problem 1.0.2 (Calculating Ext Groups) Calculate $\operatorname{Ext}_{\mathbb{Z}}^{i}(\mathbb{Z}/p,\mathbb{Z}/q)$ for distinct primes p,q. The following are several claims that are later used in the actual solution:

Claim 1: For any $m \in \mathbb{Z}$,

$$\operatorname{Hom}_{\mathbb{Z}}(\mathbb{Z}/n,\mathbb{Q}/\mathbb{Z}) \cong \mathbb{Z}/n.$$

Proof (?).

Note that there is an injection

$$1 \to \operatorname{Hom}_{\mathbb{Z}}(\mathbb{Z}/n, \mathbb{Q}/\mathbb{Z}) \hookrightarrow \operatorname{Hom}_{\mathbb{Z}}(\mathbb{Z}, \mathbb{Q}/\mathbb{Z}),$$

which follows from the fact that there is a SES

$$1 \to \mathbb{Z} \xrightarrow{x \mapsto nx} \mathbb{Z} \xrightarrow{\pi_n} \mathbb{Z}/n \to 1$$

where π_m is the canonical quotient morphism, and applying the left-exact contravariant functor $\operatorname{Hom}_{\mathbb{Z}}(\mathbb{Z}/n,\mathbb{Q}/\mathbb{Z})$ yields the first exact sequence above. We use this to identify the former as a submodule of the latter, and note that for any \mathbb{Z} -module morphism $\mathbb{Z} \xrightarrow{f} \mathbb{Q}/\mathbb{Z}$,

- 1. Since \mathbb{Z} is a free \mathbb{Z} -module with generator 1, f is entirely determined by f(1), and
- 2. f descends to a map $\tilde{f}: \mathbb{Z}/n \to \mathbb{Q}/\mathbb{Z}$ if and only if $f(n) \in \mathbb{Z}$, i.e. f(n) = [0] is in the equivalence class of zero in the quotient, and so

$$[1] = [0] = f(n) = nf(1).$$

Using this injection, we can identify the submodule $\operatorname{Hom}(\mathbb{Z}/n,\mathbb{Q}/\mathbb{Z})$ as all of those morphism $\mathbb{Z} \to \mathbb{Q}/\mathbb{Z}$ which descend to make the following diagram commute.

Link to Diagram

To characterize these, it suffices to determine all of the possible images f(1). Moreover, we can restrict our attention to coset representatives in the interval $[0,1) \cap \mathbb{Q} \subseteq \mathbb{R}$, where we want to find all $q := f(1) \in [0,1)$ such that nq = 1. A complete list of n such representatives is given by

$$q \in \left\{0, \frac{1}{n}, \frac{2}{n}, \cdots, \frac{n-1}{n}\right\}.$$

Setting $f_i(1) := \left\lfloor \frac{i}{n} \right\rfloor$ (where we take the equivalence class mod \mathbb{Z}) yields n distinct morphisms $f_i : \mathbb{Z} \to \mathbb{Q}/\mathbb{Z}$ that descend to $\tilde{f}_i : \mathbb{Z}/n \to \mathbb{Q}/\mathbb{Z}$. We can define a map

$$\Psi: \mathbb{Z} \to \operatorname{Hom}_{\mathbb{Z}}(\mathbb{Z}/n, \mathbb{Q}/\mathbb{Z})$$

 $i \mapsto f_i,$

and using the fact that if $i = i' \pmod{n}$, write i' = i + kn for some $k \in \mathbb{Z}$, then

$$f_{i'}(1) = f_{i+kn}(1) = \left[\frac{i+kn}{n}\right] = \left[\frac{i}{n} + k\right] = \left[\frac{i}{n}\right] = f_i(1),$$

since $k \in \mathbb{Z}$, so by the first isomorphism theorem Ψ descends to an isomorphism

$$\tilde{\Psi}: \mathbb{Z}/n \xrightarrow{\sim} \operatorname{Hom}_{\mathbb{Z}}(\mathbb{Z}/n, \mathbb{Q}/\mathbb{Z}).$$

Claim 2: \mathbb{Q}/\mathbb{Z} is an injective object in \mathbb{Z} -modules.

Proof (?).

By the previous exercise, it suffices to show that \mathbb{Q}/\mathbb{Z} is divisible. More generally, if any group G is divisible and $N \leq G$ is a normal subgroup, then G/N will be divisible. This follows from the fact that if $\bar{a}, \bar{b} \in G/N$ and $n \in \mathbb{Z}$, we can write $\bar{a} = a + N$ and $\bar{b} = b + N$ for some coset representatives, use divisibility to write a = nb, and then compute

$$\bar{a} = a + N = (nb) + N := n(b+N) = n\bar{b}.$$

That $\mathbb Q$ is divisible is a straightforward check: let $n \in \mathbb Z$ and $a \in \mathbb Q$, we then want a $b \in \mathbb Q$ such that a = nb, and $b \coloneqq \frac{a}{n} \in \mathbb Q$ works. Since $\mathbb Q$ is an abelian group, $\mathbb Z$ is automatically normal, and the result follows.

Claim:

$$\frac{\mathbb{Z}/n}{m(\mathbb{Z}/n)} \cong \mathbb{Z}/d \qquad \qquad d \coloneqq \gcd(\mathbb{Z}/m, \mathbb{Z}/n).$$

Proof (?).

Using

$$M \otimes_R \frac{A}{I} \cong \frac{M}{IM} \in R\text{-}\mathbf{Mod},$$

and taking

- $M := \mathbb{Z}/m$,
- $A := \mathbb{Z}$,
- $I := n\mathbb{Z}$,

we have

$$\mathbb{Z}/m \otimes_{\mathbb{Z}} \mathbb{Z}/n \cong \frac{\mathbb{Z}/m}{n(\mathbb{Z}/m)}$$
 $\in \mathbb{Z}$ -Mod.

We can now use the map

$$\varphi: \mathbb{Z} \to \mathbb{Z}/m \otimes_{\mathbb{Z}} \mathbb{Z}/n$$
$$x \mapsto x(1 \otimes 1)$$

and compute

$$\ker \varphi = \left\{ x \in \mathbb{Z} \mid x(1 \otimes 1) = 0 \right\}$$

$$= \left\{ x \in \mathbb{Z} \mid n \mid x \text{ or } m \mid x \right\}$$

$$= \langle n, m \rangle$$

$$= \langle \gcd(n, m) \rangle$$

$$:= \langle d \rangle.$$

by Bezout's theorem

Now applying the first isomorphism theorem yields the result.

Solution:

We'll follow the procedure outlined in Weibel:

- Define the contravariant functor $F(\cdot) := \operatorname{Hom}_{\mathbb{Z}}(\mathbb{Z}/p, \cdot)$, then noting that it is left-exact, it has right-derived functors.
- Find an injective resolution I of \mathbb{Z}/q .
- Write F(I) as a new (not necessarily exact) chain complex.
- Compute $\operatorname{Ext}^i_{\mathbb{Z}}(\mathbb{Z}/p,\mathbb{Z}/q) := R^i F(\mathbb{Z}/q) := H^i(F(\mathbb{Z}/q)).$

We can first take the following injective resolution:

$$1 \longrightarrow \mathbb{Z}/q \xrightarrow{d^{-1}} \mathbb{Q}/\mathbb{Z} \xrightarrow{d^0} \mathbb{Q}/\mathbb{Z} \xrightarrow{d^1} 1$$
$$[1]_q \longrightarrow \left[\frac{1}{q}\right]$$

$$[x] \longrightarrow [qx]$$

Link to Diagram

This is a chain complex by construction, since $d^2([1]_q) = \left[q\left(\frac{1}{q}\right)\right] = [1] = [0]$. We now delete the augmentation and apply $F(\cdot)$:

$$1 \longrightarrow I^0 \coloneqq \mathbb{Q}/\mathbb{Z} \xrightarrow{d^0} I^1 \coloneqq \mathbb{Q}/\mathbb{Z} \xrightarrow{d^1} 1$$

$$\downarrow F(\cdot) \downarrow \downarrow f(\cdot) \downarrow f(\cdot)$$

Link to Diagram

Here we immediately simplify by applying the isomorphism from the earlier claim. Noting that $d^0(x) := qx$ was multiplication by q, we have $\partial^0(f) = d^0 \circ f$ is post-composition by the multiplication by q map, and $\tilde{\partial}^0$ similarly becomes multiplication by q.

We now take homology:

$$\operatorname{Ext}_{\mathbb{Z}}^{1}(\mathbb{Z}/p,\mathbb{Z}/q) \coloneqq R^{1}F(\mathbb{Z}/q) \coloneqq \frac{\ker \partial^{1}}{\operatorname{im} \partial^{0}} = \frac{\mathbb{Z}/p}{q(\mathbb{Z}/p)} \cong \mathbb{Z}/d\mathbb{Z} \cong 1,$$

where $d := \gcd(p, q) = 1$ if p, q are coprime.

Problem 1.0.3 (Weibel 2.3.2)

Let $A \in \mathbf{Ab}$, and show that the following map is injective:

$$\begin{split} \varepsilon_A: A \to I(A) \coloneqq \prod_{f \in \operatorname{Hom}_{\mathbf{Ab}}(A, \mathbb{Q}/\mathbb{Z})} \mathbb{Q}/\mathbb{Z} \\ a \mapsto \mathbf{a} \text{ where } \mathbf{a}(f) \coloneqq f(a) \in \mathbb{Q}/\mathbb{Z}, \end{split}$$

i.e. when looking at the image $\varepsilon_A(a)$ in the product, the component indexed by f is an element of \mathbb{Q}/\mathbb{Z} obtained by evaluating f(a).

Hint: if $a \in A$, find a map $f : a\mathbb{Z} \to \mathbb{Q}/\mathbb{Z}$ with $f(a) \neq 0$ and extend this to a map $f' : A \to \mathbb{Q}/\mathbb{Z}$.

Solution:

By contrapositive, we'll suppose $a \neq 0$ and show $\varepsilon_A(a) \neq 0$. Following the hint, we first consider the cyclic subgroup $a\mathbb{Z} = \{an \mid n \in \mathbb{Z}\}$ and define a map

$$f_a: a\mathbb{Z} \to \mathbb{Z}$$

$$an \mapsto n.$$

We now pick $\ell > 1 \in \mathbb{Z}$ to be any integer, and define a composition $f : a\mathbb{Z} \to \mathbb{Q}/\mathbb{Z}$:

Link to Diagram

By choice of ℓ , this map satisfies $f(a) = [1/\ell] \neq 0$, so the map is nonzero. Since \mathbb{Q}/\mathbb{Z} is injective, the universal property provides a lift \tilde{f} :

Link to Diagram

Since \tilde{f} lifts f, it is also nonzero. But now we can check that

$$\varepsilon_A(a)(f) := f(a) \neq 0,$$

so the f component of the image of a is nonzero and thus $\mathbf{a} := \varepsilon_A(a) \neq 0$ in the product.

Problem 1.0.4 (Weibel 2.4.2)

If $U: \mathcal{B} \to \mathcal{C}$ is right-exact functor, show that

$$U(L_iF) \cong L_i(UF)$$
.

Solution:

We'll show that $(U \circ L_i F)(X) \cong (L_i(U \circ F))(X)$ for every object X. Starting with the left-hand side, to compute left-derived functors, we'll need projective resolutions, so let $P \to X$ be a projective resolution of X. Fixing labeling, we have the following situation:

$$\cdots \longrightarrow P_2 \xrightarrow{\partial_2} P_1 \xrightarrow{\partial_1} P_0 \xrightarrow{\varepsilon} X \xrightarrow{0} 0$$

$$\downarrow F(\cdot)$$

$$\cdots \longrightarrow FP_2 \xrightarrow{F(\partial_2)} FP_1 \xrightarrow{F(\partial_1)} FP_0 \xrightarrow{0} 0$$

Link to Diagram

We now have by definition

$$L_i F(X) \coloneqq \frac{\ker F(\partial_i)}{\operatorname{im} F(\partial_{i+1})} \implies U(L_i F(X)) \coloneqq U\left(\frac{\ker F(\partial_i)}{\operatorname{im} F(\partial_{i+1})}\right).$$

For the right-hand side, we can take the same projective resolution $P \to X$, and apply a similar process:

$$\cdots \longrightarrow P_2 \xrightarrow{\partial_2} P_1 \xrightarrow{\partial_1} P_0 \xrightarrow{\varepsilon} X \xrightarrow{0} 0$$

$$\downarrow (U \circ F)(\cdot)$$

$$\cdots \longrightarrow UFP_2 \xrightarrow{(UF)(\partial_2)} UFP_1 \xrightarrow{(UF)(\partial_1)} UFP_0 \xrightarrow{0} 0$$

Link to Diagram

Again, by definition,

$$(L_i(UF))(X) := \frac{\ker(UF)(\partial_i)}{\operatorname{im}(UF)(\partial_{i+1})},$$

and thus it suffices to show that there is an isomorphism

$$U\left(\frac{\ker F(\partial_i)}{\operatorname{im} F(\partial_{i+1})}\right) \xrightarrow{\sim} \frac{\ker(UF)(\partial_i)}{\operatorname{im}(UF)(\partial_{i+1})}.$$

To show this, we apply the exact functor U to the following SES to produce a new SES, from which we'll produce the desired isomorphism f:

$$0 \longrightarrow \operatorname{im} F(\partial_{i+1}) \xrightarrow{\iota_{i}} \operatorname{ker} F(\partial_{i}) \xrightarrow{\pi_{i}} \frac{\operatorname{ker} F(\partial_{i})}{\operatorname{im} F(\partial_{i+1})} \longrightarrow 0$$

$$0 \longrightarrow U \left(\operatorname{im} F(\partial_{i+1})\right) \xrightarrow{U(\iota_{i})} U \left(\operatorname{ker} F(\partial_{i})\right) \xrightarrow{U(\pi_{i})} U \left(\frac{\operatorname{ker} F(\partial_{i})}{\operatorname{im} F(\partial_{i+1})}\right) \longrightarrow 0$$

$$0 \longrightarrow U \left(\operatorname{im} F(\partial_{i+1})\right) \xrightarrow{U(\iota_{i})} U \left(\operatorname{ker} F(\partial_{i})\right) \xrightarrow{\tilde{\pi}_{i}} \frac{U(\operatorname{ker} F(\partial_{i}))}{U(\operatorname{im} F(\partial_{i+1}))} \longrightarrow 0$$

Link to Diagram

Here $\tilde{\pi}_i$ is the natural quotient map, whose image is $\operatorname{coker} U(\iota_i)$. Finally, the map f exists an any abelian category, using that whenever $0 \to A \xrightarrow{g_1} B \xrightarrow{g_2} C \to 0$ is exact, there is an isomorphism $C \xrightarrow{\sim} B/\operatorname{im}(g_1)$.

Problem 1.0.5 (Weibel 2.4.3)

• If $0 \to M \to P \to A \to 0$ is exact with P projective or F-acyclic, show that

$$L_iF(A) \cong L_{i-1}FM$$

 $i \geq 2$.

• Show that if

$$0 \to M_m \to P_m \to P_{m-1} \to \cdots \to P_0 \to A \to 0$$

is exact with P_i projective or F-acyclic, then

$$L_i F(A) \cong L_{i-m-1} F(M_m)$$
 $i \ge m+2.$

- Moreover show that $L_{m+1}F(A)$ is the kernel of $F(M_m) \to F(P_m)$.
- Conclude that if $P \to A$ is an F-acyclic resolution of A, then $L_iF(A) = H_i(F(P))$.

Solution:

Claim:

$$L_i F(A) \cong L_{i-1} FM$$
 $i \ge 2.$

Proof (of claim).

Following the proof of Weibel Theorem 2.4.6, let $P_M \to M$ and $P_A \to A$ be projective resolutions of M and A respectively. Then applying the Horseshoe Lemma, there is a projective resolution $P_P \to P$ of P such that the following is a short exact sequence of chain complexes:

$$0 \to P_M \to P_P \to P_A \to 0$$
,

where in fact in each degree n piece, this is induces a *split* exact sequence. Using that F is additive and additive functors preserve split exact sequences, the following is a SES for every n:

$$0 \to FP_M^n \to FP_P^n \to FP_A^n \to 0$$
,

which implies that there is a SES of chain complexes

$$0 \to FP_M \to FP_P \to FP_A \to 0.$$

Thus there is an associated LES of derived functors:

Link to Diagram

Using that P is F-acyclic, the middle terms $L_iFP = 0$ for all i > 0, and thus this splits into a collection of SESs:

$$0 \to L_2FA \xrightarrow{\partial_2} L_1FM \to 0$$

$$0 \to L_3FA \xrightarrow{\partial_3} L_2FM \to 0$$

$$\vdots$$

$$0 \to L_iFA \xrightarrow{\partial_3} L_{i-1}FM \to 0.$$

This makes every ∂_i for $i \geq 2$ an isomorphism.

Claim:

$$L_iFA \cong \ker(FM \to FP).$$

Proof(?).

Using the same argument as above, consider the lower order terms of the associated LES:

Link to Diagram

Noting that $L_1FP = 0$ by F-acyclicity, the highlighted portion forms a four term exact sequence. We can form another exact sequence and compare the two:

Link to Diagram

That the map indicated by the dotted line exists and is an isomorphism holds in any abelian category, using that fact that whenever $0 \to A \to B \xrightarrow{f} C \to 0$ is a SES we have $A \cong \ker f$.

Claim: If $P \to A$ is an F-acyclic resolution of A, then there is an isomorphism

$$L_iFA \cong H_i(FP)$$
.

Problem 1.0.6 (Weibel 2.5.2)

Show that the following are equivalent:

- a. A is a projective R-module.
- b. $\operatorname{Hom}_R(A, \cdot)$ is an exact functor.
- c. $\operatorname{Ext}_R^{i\neq 0}(A,B)=0$ and for all B, i.e. A is $\operatorname{Hom}_R(\,\cdot\,,B)$ -acyclic for all B.
- d. $\operatorname{Ext}_{R}^{1}(A,B)$ vanishes for all B.

Proof $(a \iff b)$.

Let ξ be the following SES:

$$\xi: 0 \to M_1 \xrightarrow{f} M_2 \xrightarrow{g} M_3 \to 0$$

and define the functor $F(\cdot) := \operatorname{Hom}_R(A, \cdot)$. This is a covariant left-exact functor, and so applying it to the above sequence yields

$$0 \longrightarrow M_1 \xrightarrow{f} M_2 \xrightarrow{g} M_3 \longrightarrow 0$$

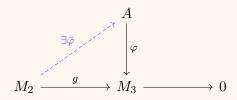

$$\parallel F(\cdot) := \operatorname{Hom}_R(A, \cdot) \qquad \qquad \downarrow$$

$$0 \longrightarrow FM_1 \xrightarrow{F(f): \lambda \mapsto f \circ \lambda} FM_2 \xrightarrow{F(g): \lambda \mapsto g \circ \lambda} FM_3$$

Link to Diagram

 \Longrightarrow

For F to be exact, it suffices to show it is right-exact, i.e. that F(g) is surjective. This amounts to asking that every $\varphi \in FM_3 := \operatorname{Hom}_R(A, M_3)$ lifts to a preimage $\tilde{\varphi} \in FM_2 := \operatorname{Hom}_R(A, M_2)$ satisfying $F(g)(\tilde{\varphi}) = \varphi$. Unwinding definitions, this requires that $g \circ \tilde{\varphi} = \varphi$, which is precisely the lift required for the universal property of projective objects:

Link to Diagram

If A is projective, this lift always exists, so $\operatorname{Hom}_R(A, \cdot)$ is an exact functor. Conversely, if $\operatorname{Hom}_R(A, \cdot)$ is exact, this lift always exists, so A satisfies the universal property of a projective object.

Proof (?).

Let ξ be a SES, then apply $F(\cdot) := \operatorname{Hom}_R(A, \cdot)$ to ξ to obtain an associated LES:

$$\xi: \qquad 0 \longrightarrow M_1 \xrightarrow{f} M_2 \xrightarrow{g} M_3 \longrightarrow 0$$

$$F\xi: \qquad 0 \longrightarrow \operatorname{Hom}_R(A, M_1) \xrightarrow{F(f)} \operatorname{Hom}_R(A, M_2) \xrightarrow{F(g)} \operatorname{Hom}_R(A, M_3)$$

$$\operatorname{Ext}_R^1(A, M_1) \xrightarrow{L_1F(f)} \operatorname{Ext}_R^1(A, M_2) \xrightarrow{L_1F(g)} \operatorname{Ext}_R^1(A, M_3)$$

$$\operatorname{Ext}_R^2(A, M_1) \xrightarrow{L_2F(f)} \cdots$$

- Link to Diagram
- $a \implies b$: If M is projective,
- $b \implies c$: If F is exact, then $F\xi$ is the SES $0 \to FC \to FB \to FA \to 0$. In particular, we have
 - $-L_1FC \cong \operatorname{coker} F(g) \cong 0,$
 - $-L_1FB \cong \operatorname{coker} \delta_0 = L_1FC/\operatorname{im} \delta_0 \cong 0/\operatorname{im} \delta_0 \cong 0,$
 - $-L_1FA \cong \operatorname{coker} L_1F(f) \cong L_1FB/\operatorname{im} L_1F(f) \cong 0/\operatorname{im} L_1F(f) \cong 0$, etc.

Thus all of the higher terms are iterated cokernels, and inductively since all of the numerators are zero, $L_iF(\cdot)$

• $c \implies d$: This is clear, since i = 1 is one of the values of i that occurs in the statement of (c).

We can then use the fact that $\operatorname{Ext}_R^i(X,M) := L_i \operatorname{Hom}_R(X,B)$ for X = A,B,C and apply corollary 2.4.2: if A is projective then $L_i F(A) = 0$ for all $i \neq 0$ for any functor F. So all of the Ext^i above for i > 1 vanish, collapsing the LES down to a SES, which means that $F(\xi)$ is again a SES, so F preserves all short-exact sequences and by definition is exact.

Problem 1.0.7 (Weibel 2.6.4)

Show that colim is left adjoint to Δ , and conclude that colim is right-exact when when \mathcal{A} is abelian and colim exists. Show that the pushout, i.e. $\bullet \leftarrow \bullet \rightarrow \bullet$, is not an exact functor on \mathbf{Ab} .
