We saw an interesting example of a function field in more than one variable which showed that valuations of rank larger than 1 can arise, but this does not happen for one variable function fields. That is, for K/k of transcendence degree 1, all valuations on K which are trivial on k are discrete. We'll now want to go farther and describe the places  $\Sigma(K/k)$ , which will be the set of points on an algebraic curve. Scheme-theoretically, this will literally be the set of closed points on a certain projective curve whose function field is K. Note that a priori, finding closed points on a curve over an arbitrary field is hard!

Recall that if A is a Dedekind domain such that  $\mathrm{ff}(A) = K$ , then for all  $\mathfrak{p} \in \mathrm{mSpec}(A)$  there exists a discrete valuation  $v_p$  on K. I.e., every maximal ideal induces a discrete valuation that is A-regular, so the valuation ring will contain A. How is this obtained? Take a nonzero  $x \in K^{\times}$ , and take the corresponding principal fractional ideal  $\langle x \rangle := Ax$ , which we can factor in a Dedekind domain as  $Ax = \prod_{\mathfrak{p} \in \mathrm{mSpec}(A)} \mathfrak{p}^{\alpha_{\mathfrak{p}}}$  with  $\alpha_{\mathfrak{p}} \in \mathbb{Z}$ . This looks like an infinite product, but for any fixed x, only

finitely many  $\alpha$  are nonzero. Note that these  $\alpha$  are exactly what we're looking for: the  $\mathfrak{p}$ -adic evaluation of x is given precisely by  $v_{\mathfrak{p}}(x) := \alpha_{\mathfrak{p}}$ , where we are using unique factorization of ideals in Dedekind domains. Thus we have a map

$$v: \mathrm{mSpec}(A) \to \Sigma(K/A)$$
  
 $\mathfrak{p} \mapsto v_{\mathfrak{p}}.$ 

So this sends a maximal ideal to a place that is A-regular, and it turns out to be a bijection.

## Proposition 1.0.1(?).

The map v is a bijection, and thus we may write

$$\Sigma(K/A) \cong \mathrm{mSpec}(A).$$

Proof(?).

Claim: v is injective.

If  $\mathfrak{p}_1, \mathfrak{p}_2 \in \mathrm{mSpec}(A)$  are two different maximal ideals. Then there exists an element  $x \in \mathfrak{p}_1 \setminus \mathfrak{p}_2$ , and so  $x^{-1} \in A_{\mathfrak{p}_2} \setminus A_{\mathfrak{p}_1}$ . This follows since if x is not in  $\mathfrak{p}_2$ , its  $\mathfrak{p}_2$ -adic valuation is zero, and thus the  $\mathfrak{p}_2$ -adic valuation of  $x^{-1}$  is -0 = 0 as well. On the other hand, since  $x \in \mathfrak{p}_1$ , its  $\mathfrak{p}_1$ -adic valuation is positive and therefore  $v_{\mathfrak{p}_1}(x^{-1}) < 0$  and  $x^{-1}$  is not in  $A_{\mathfrak{p}_1}$ .

Claim: v is surjective.

Let  $v \in \Sigma(K/A)$ , so  $A \subset R_v$ , i.e. take a valuation whose valuation ring contains A. Note that we're not assuming the valuation is discrete, this can be a general Krull valuation, but we're trying to show it's equal to a certain p-adic valuation. As always with a subring of a valuation ring, we can pull back the maximal ideal and consider  $\mathfrak{m}_v \cap A \in \operatorname{Spec}(A)$ . We're hoping that this is a maximal ideal, since maximals correspond to valuations. Since we're in a Dedekind

1 Lecture 5A

domain, the only prime ideal we don't want this to be is the zero ideal of A, so suppose it were. Then  $A^{\bullet} \subset R_v^{\times}$ , and so  $K^{\times} \subset R_v^{\times}$ . This is because the only element of the maximal ideal that lies in A is zero, so every nonzero element of A is not in this maximal ideal and is thus a unit. But for any unit, its inverse is also a unit, yielding the inclusion  $K^{\times} \subset R_v^{\times}$ . The only way this could possibly happen is if  $R_v = K$ , which yields the trivial valuation ring. However, by definitio
