	.1 Notions of "smallness" in $\mathbb{R}$

## 1 Lecture 1 (Thu 15 Aug 2019 11:04)

See Folland's Real Analysis, definitely a recommEnded reference.

Possible first day question: how can we "measure" a subset of  $\mathbb{R}$ ? We'd like bigger sets to have a higher measure, we wouldn't want removing points to increase the measure, etc. This is not quite possible, at least something that works on *all* subsets of  $\mathbb{R}$ . We'll come back to this in a few lectures.

#### 1.1 Notions of "smallness" in $\mathbb R$

**Definition 1.** Let E be a set, then E is *countable* if it is in a one-to-one correspondence with  $E' \subseteq \mathbb{N}$ , which includes  $\emptyset, \mathbb{N}$ .

**Definition 2.** A set E is meager (or of 1st category) if it can be written as a countable union of nowhere dense sets.

**Exercise 1.** Show that any finite subset of  $\mathbb{R}$  is meager.

Intuitively, a set is *nowhere dense* if it is full of holes. Recall that a  $X \subseteq Y$  is dense in Y iff the closure of X is all of Y. So we'll make the following definition:

**Definition 3.** A set  $A \subseteq \mathbb{R}$  is nowhere dense if every interval I contains a subinterval  $S \subseteq I$  such that  $S \subseteq A^c$ .

Note that a finite union of nowhere dense sets is also nowhere dense, which is why we're giving a name to such a countable union above. For example,  $\mathbb{Q}$  is an infinite, countable union of nowhere dense sets that is not itself nowhere dense.

Equivalently,

- $A^c$  contains a dense, open set.
- The interior of the closure is empty.

We'd like to say something is measure zero exactly when it can be covered by intervals whose lengths sum to less than  $\varepsilon$ .

**Definition 4.** Definition: E is a *null set* (or has *measure zero*) if  $\forall \varepsilon > 0$ , there exists a sequence of intervals  $\{I_j\}_{j=1}^{\infty}$  such that

$$E \subseteq \bigcup_{j=1}^{\infty} \text{ and } \sum |I_j| < \varepsilon.$$

Exercise 2. Show that a countable union of null sets is null.

We have several relationships

- $\bullet$  Countable  $\implies$  Meager, but not the converse.
- $\bullet$  Countable  $\implies$  Null, but not the converse.

**Exercise 3.** Show that the "middle third" Cantor set is not countable, but is both null and meager. Key point: the Cantor set does not contain any intervals.

**Theorem 1.** Every  $E \subseteq \mathbb{R}$  can be written as  $E = A \coprod B$  where A is null and B is meager.

This gives some information about how nullity and meagerness interact – in particular,  $\mathbb{R}$  itself is neither meager nor null. Idea: if meager  $\implies$  null, this theorem allows you to write  $\mathbb{R}$  as the union of two null sets. This is bad!

*Proof.* We can assume  $E = \mathbb{R}$ . Take an enumeration of the rationals, so  $\mathbb{Q} = \{q_j\}_{j=1}^{\infty}$ . Around each  $q_j$ , put an interval around it of size  $1/2^{j+k}$  where we'll allow k to vary, yielding multiple intervals around  $q_j$ . To do this, define  $I_{j,k} = (q_j - 1/2^{j+k}, q_j + 2^{j+k})$ . Now let  $G_k = \bigcup_j I_{j,k}$ . Finally, let  $A = \bigcap_k G_k$ ; we claim that A is null.

Note that  $\sum_{j} |I_{j,k}| = \frac{1}{2^k}$ , so just pick k such that  $\frac{1}{2^k} < \varepsilon$ .

Now we need to show that  $A^c$ :

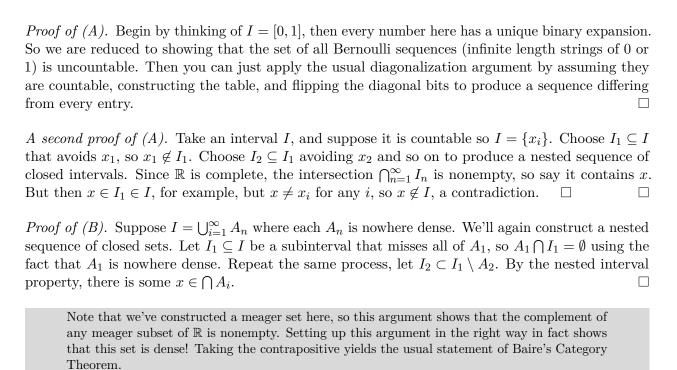

B is meager. Note that  $G_k$  covers the rationals, and is a countable union of open sets, so it is dense. So  $G_k$  is an open and dense set. By one of the equivalent formulations of meagerness, this means that  $G_k^c$  is nowhere dense. But then  $B = \bigcup_k G_k^c$  is meager.

#### 1.2 $\mathbb{R}$ is not small

Theorem 2.

- A (Cantor):  $\mathbb{R}$  is not countable.
- B (Baire):  $\mathbb{R}$  is not meager. (Baire Category Theorem)
- C (Borel):  $\mathbb{R}$  is not null.

Note that theorems B and C imply theorem A. You can also replace  $\mathbb{R}$  with any nonempty interval I = [a, b] where a < b. This is a strictly stronger statement – if any subset of  $\mathbb{R}$  is not countable, then certainly  $\mathbb{R}$  isn't, and so on.

Consider the Thomae function:

It is continuous on  $\mathbb{Q}$ , but discontinuous on  $\mathbb{R} \setminus \mathbb{Q}$ . Can this be switched to get some function f that is continuous on  $\mathbb{R} \setminus \mathbb{Q}$  and discontinuous on  $\mathbb{Q}$ ? The answer is no. The set of discontinuities of a function is *always* an  $F_{\sigma}$  set, and  $\mathbb{R} \setminus \mathbb{Q}$  is not one. Equivalently, the rationals are not a  $G_{\delta}$  set.

Some facts:

- The pointwise limit of continuous functions has a meager set of discontinuities.
- If f is integrable, the set of discontinuities is null.
- ullet If f is monotone, they are countable.
- There is a continuous nowhere differentiable function: let  $f(x) = \sum_{n} \frac{\|10^n x\|}{10^n}$ , and in fact most functions are like this.
- If f is continuous and monotone, the discontinuities are null.

**Theorem 3.** Let I = [a, b]. If  $I \subseteq \bigcup_{i=1}^{\infty} I_i$ , then  $|I| \leq \sum_{i=1}^{\infty} |I_i|$ .

*Proof.* The proof is by induction. Assume  $I \subseteq \bigcup_n^{N+1} I_n$ , where wlog we can assume that  $a < a_{N+1} < b \le b_{N+1}$ , then  $[a, a_{N+1}] \subset \bigcup_{n=1}^N I_n$  so the inductive hypothesis applies. But then  $b-a \le b_{N+1}-a=(b_{N+1}-a_{N+1})+(a_{N+1}-a) \le \sum_{n=1}^{N+1} |I_n|$ .

Note that this proves that the reals are uncountable!
