Question: how do we define $h_{V,D}$?

Answer: write $D = D_1 - D_2$ which are (very) ample divisors and basepoint free. We then obtain embeddings

$$\varphi_1: V \hookrightarrow \mathbb{P}_K^{n_1}$$
$$\varphi_2: V \hookrightarrow \mathbb{P}_K^{n_2}.$$

So write

$$h_{V,D}(p) = h(\varphi_1(p)) - h(\varphi_2(p)) + O(1)$$

Example 1.1.

For E/K an elliptic curve,

- 2[0] is an ample divisor
- 3[0] is a very ample divisor.

Let K be a local field (i.e. \mathbb{C}, \mathbb{R} , a p-adic field, or $\mathbb{F}_q((t))$ formal Laurent series) and A/K be an abelian variety; we want to understand A(K). We know this has the structure of compact abelian K-analytic Lie group.

- Question 1: What does Lie theory say?
- Question 2: What extra information comes from A/K being a g-dimensional abelian variety?

If
$$K = \mathbb{C}$$
, then $A(K) \cong (\mathbb{R}/\mathbb{Z})^{2g}$. If $K = \mathbb{R}$, then $A(K) \cong (\mathbb{R}/\mathbb{Z})^g \oplus \prod_{i=1}^d \mathbb{Z}/2\mathbb{Z}$ where $0 \leq d \leq g$.

Fix d, then

- Let E_1/\mathbb{R} with $\Delta > 0$ (and thus 3 real roots), then $E_1(\mathbb{R})[2] = (\mathbb{Z}/2\mathbb{Z})^2$. Let E_2/\mathbb{R} with $\Delta < 0$ (and 1 real root), then $E_2(\mathbb{R})[2] = \mathbb{Z}/2\mathbb{Z}$.

By taking products of E_1 and E_2 , i.e. $A = (E_1)^d \times (E_2)^{g-d}$.

Todo: find reference in Silverman?
