		Isotopy	
	1.3	Self-Homeomorphisms	
	1.4	Dehn Twists	

# **1** Friday, September 25

All manifolds: connected, oriented, 2nd countable, Hausdorff.

#### 1.1 Compact-Open Topology

• For X, Y topological spaces, consider

$$Y^X = C(X,Y) = \text{hom}_{\text{Top}}(X,Y) \coloneqq \{f : X \to Y \mid f \text{ is continuous}\}.$$

- General idea: it's nice to cartesian closed categories, which require exponential objects or internal homs: i.e. for every hom set, there is some object in the category that represents it (i.e. here we'd like the homs to again be spaces).
- Can make this work if we assume WHCG: weakly Hausdorff and compactly generated.
  - \* Weakly Hausdorff: every continuous image of a compact Hausdorff space into it is closed.
  - \* Compactly generated: sets are closed iff their intersection with every compact subspace is closed.
- Topologize with the compact-open topology  $\mathcal{O}_{\text{CO}}$ :

$$U \in \mathcal{O}_{\mathrm{CO}} \iff \forall f \in U, \quad f(K) \subset Y \text{ is open for every compact } K \subseteq X.$$

\* If Y = (Y, d) is a metric space, this is the topology of "uniform convergence on compact sets": for  $f_n \to f$  in this topology iff

$$||f_n - f||_{\infty,K} := \sup \left\{ d(f_n(x), f(x)) \mid x \in K \right\} \stackrel{n \to \infty}{\to} 0 \quad \forall K \subseteq X \text{ compact.}$$

In words:  $f_n \to f$  uniformly on every compact set.

- If X itself is compact and Y is a metric space, C(X,Y) can be promoted to a metric space with  $d(f,g) = \sup_{x \in Y} (f(x),g(x))$ .
- Useful in analysis: when is a family of functions  $\mathcal{F} = \{f_{\alpha}\} \subset \hom_{\text{Top}}(X, Y)$  compact? Essentially answered by Arzela-Ascoli

#### Theorem 1.1(Ascoli).

If X is locally compact Hausdorff and (Y, d) is a metric space, a family  $\mathcal{F} \subset \text{hom}_{\text{Top}}(X, Y)$  has compact closure  $\iff \mathcal{F}$  is equicontinuous and  $F_x \coloneqq \{f(x) \mid f \in \mathcal{F}\} \subset Y$  has compact closure.

#### Corollary 1.2(Arzela).

If  $\{f_n\} \subset \text{hom}_{\text{Top}}(X,Y)$  is an equicontinuous sequence and  $F_x := \{f_n(x)\}$  is bounded for every X, it contains a uniformly convergent subsequence.

- Useful in Number Theory / Rep Theory / Fourier Series: can take G to be a locally compact abelian topological group and define its Pontryagin dual  $\widehat{G} := \hom_{\text{TopGrp}}(G, S^1)$  where we consider  $S^1 \subset \mathbb{C}$ .
  - \* Can integrate with respect to the Haar measure  $\mu$ , define  $L^p$  spaces, and for  $f \in L^p(G)$  define a Fourier transform  $\widehat{f} \in L^p(\widehat{G})$ .

$$\widehat{f}(\chi) \coloneqq \int_G f(x) \overline{\chi(x)} d\mu(x).$$

• So define

 $\operatorname{Map}(X,Y) \coloneqq (\operatorname{hom}_{\operatorname{Top}}(X,Y), \mathcal{O}_{\operatorname{CO}})$  where  $\mathcal{O}_{\operatorname{CO}}$  is the compact-open topology.

 $Map(X,Y) = hom_{Top}(X,Y)$  equipped with the compact-open topology.

- Can immediately consider some interesting spaces via the functor Map $(\cdot, Y)$ :

$$\begin{split} X &= \{ \mathrm{pt} \} \leadsto & \mathrm{Map}(\{ \mathrm{pt} \}, Y) \cong Y \\ X &= I \leadsto & \mathcal{P}Y \coloneqq \{ f : I \to Y \} = Y^I \\ X &= S^1 \leadsto & \mathcal{L}Y \coloneqq \left\{ f : S^1 \to Y \right\} = Y^{S^1}. \end{split}$$

Note: take basepoints to obtain the base path space PY, the based loop space  $\Omega Y$ .

- Importance in homotopy theory: the path space fibration  $\Omega(Y) \hookrightarrow P(Y) \xrightarrow{\gamma \mapsto \gamma(1)} Y$  (plays a role in "homotopy replacement", allows you to assume everything is a fibration and use homotopy long exact sequences).
- Adjoint property: there is a homeomorphism

$$\operatorname{Map}(X \times Z, Y) \leftrightarrow_{\cong} \operatorname{Map}(Z, \operatorname{Map}(X, Y))$$
$$H: X \times Z \to Y \iff \tilde{H}: Z \to \operatorname{Map}(X, Y)$$
$$(x, z) \mapsto H(x, z) \iff z \mapsto H(\cdot, z).$$

Categorically, hom $(X, \cdot) \leftrightarrow (X \times \cdot)$  form an adjoint pair in Top.

A form of this adjunction holds in any cartesian closed category.

- Fun fact: with some mild point-set conditions (Locally compact and Hausdorff),

$$\pi_0 \operatorname{Map}(X, Y) = \{ [f], \text{ homotopy classes of maps } f : X \to Y \},$$

i.e. two maps f, g are homotopic  $\iff$  they are connected by a path in Map(X, Y).

\* Proof:

$$\mathcal{P}\mathrm{Map}(X,Y) = \mathrm{Map}(I,\mathrm{Map}(X,Y)) \cong \mathrm{Map}(Y \times I,X),$$

and just check that  $\gamma(0) = f \iff H(x,0) = f$  and  $\gamma(1) = g \iff H(x,1) = g$ .

- \* Note that we can interpret the RHS as the space of paths
- Now we can bootstrap up to play fun recursive games by applying the pathspace endofunctor  $\operatorname{Map}(I, \cdot)$ : define

$$\operatorname{Map}_{I}^{1}(X, Y) := \operatorname{Map}(I, \operatorname{Map}(X, Y)) = \mathcal{P}\operatorname{Map}(X, Y)$$

and then

$$\begin{aligned} \operatorname{Map}_{I}^{2}(X,Y) &\coloneqq \operatorname{Map}(I,\operatorname{Map}_{I}^{1}(X,Y)) \\ &\cong \operatorname{Map}(I,\operatorname{Map}(I,\operatorname{Map}(X,Y))) &= \mathcal{P}(\mathcal{P}(X,Y)) \\ &\cong \operatorname{Map}(I,\operatorname{Map}(Y\times I,X)) \\ &\coloneqq \mathcal{P}\operatorname{Map}(Y\times I,X). \end{aligned}$$

Interpretation: we can consider paths in the *space* of paths, and paths between homotopies, and homotopies between homotopies, ad infinitum!

This in fact defines a monad on spaces: an endofunctor that behaves like a monoid.

#### 1.2 Isotopy

???

#### 1.3 Self-Homeomorphisms

- In any category, the automorphisms form a group.
  - In a general category  $\mathcal{C}$ , we can always define the group  $\operatorname{Aut}_{\mathcal{C}}(X)$ .
    - \* If the group has a topology, we can consider  $\pi_0 \operatorname{Aut}_{\mathcal{C}}(X)$ , the set of path components.
    - \* Since groups have identities, we can consider  $\operatorname{Aut}^0_{\mathcal{C}}(X)$ , the path component containing the identity.
  - So we make a general definition, the extended mapping class group:

$$MCG_{\mathcal{C}}^{\pm}(X) := Aut_{\mathcal{C}}(X)/Aut_{\mathcal{C}}^{0}(X).$$

- Here the  $\pm$  indicates that we take both orientation preserving and non-preserving automorphisms.
- Has an index 2 subgroup of orientation-preserving automorphisms,  $MCG^+(X)$ .
- Now restrict attention to

$$\operatorname{Homeo}(X) := \operatorname{Aut}_{\operatorname{Top}}(X) = \left\{ f \in \operatorname{Map}(X, X) \mid f \text{ is an isomorphism} \right\}$$
 equipped with  $\mathcal{O}_{\operatorname{CO}}$ .

- Taking  $MCG_{Top}^{\pm}(X)$  yields ??

• Similarly, we can do all of this in the smooth category:

$$Diffeo(X) := Aut_{C^{\infty}}(X).$$

- Taking  $MCG_{C^{\infty}}(X)$  yields ??
- Similarly, we can do this for the homotopy category of spaces:

$$ho(X) := \{ [f] \}$$
.

- Taking MCG(X) here yields homotopy classes of self-homotopy equivalences.
- For topological manifolds: Isotopy classes of homeomorphisms
  - In the compact-open topology, two maps are isotopic iff they are in the same component of  $\pi \operatorname{Aut}(X)$ .
- For surfaces: MCG(S) on the Teichmuller space T(S), yielding a SES

$$0 \to \mathrm{MCG}(S) \to T(S) \to \widetilde{\mathcal{M}}_q(S) \to 0$$

where the last term is the moduli space of Riemann surfaces homeomorphic to X.

- -T(S) is the moduli space of complex structures on S, up to the action of homeomorphisms that are isotopic to the identity:
  - \* Points are isomorphism classes of marked Riemann surfaces
- Used in the Neilsen-Thurston Classification (for a compact orientable surface, a self-homeomorphism is isotopic to one which is any of: periodic: reducible (preserves some simple closed curves), or pseudo-Anosov (has directions of expansion/contraction))
- Generated by Dehn twists: a self homeomorphism
- Any finite group is MCG(X) for some compact hyperbolic 3-manifold X.

Theorem 1.3 (Dehn-Neilsen-Baer).

$$MCG^{\pm}(\Sigma_q) \cong Out(\pi_1(\Sigma_q)).$$

#### 1.4 Dehn Twists

Claim: Let  $A := \{z \in \mathbb{C} \mid 1 \le |z| \le 2\}$ , then  $MCG(A) \cong \mathbb{Z}$ , generated by the map

$$\tau_0: \mathbb{C} \to \mathbb{C}$$
  
 $z \mapsto \exp(2\pi i |z|) z.$
