### 1.1 Problem 1

Todo

# 1.2 Problem 2

We can note that since f has 4 roots, the Galois group G of its splitting field will be a subgroup of  $S_4$ . Moreover, G must be a transitive subgroup of  $S_4$ , i.e. the action of G on the roots of f should be transitive. This reduces the possibilities to  $G \cong S^4$ ,  $A^4$ ,  $D^4$ ,  $\mathbb{Z}_4$ ,  $\mathbb{Z}_2^2$ .

Since f has exactly 2 real roots and thus a pair of roots that are complex conjugates, the automorphism given by complex conjugation is an element of G. But this corresponds to a 2-cycle  $\tau = (ab)$ , and we can then make the following conclusions:

- Not  $A_4$ :  $A_4$  contains only even cycles, and  $\tau$  is odd.
- Not  $Z_4$ : This subgroup is generated by a single 4-cycle  $\sigma$ , which up to conjugacy is (1234), and  $\sigma^n$  is not a 2-cycle for any n.

• Not  $\mathbb{Z}_2^2$ : In order to be transitive, this subgroup must be  $\{e, (12)(34), (13)(24), (14)(23)\}$ , which does not contain  $\tau$ .

The only remaining possibilities are  $S^4$  and  $D^4$ .

#### 1.3 Problem 3

#### 1.3.1 Part 1

To see that  $\phi(n)$  is even for all n > 2, we can take a prime factorization of n and write

$$\phi(n) = \phi\left(\prod_{i=1}^m p_i^{k_i}\right) = \prod_{i=1}^m \phi(p_i^{k_i}) = \prod_{i=1}^m p^{k_i-1}(p-1) = \prod_{i=1}^m p^{k_i-1} \prod_{i=1}^m (p-1)$$

where each  $k_i \ge 1 \implies k_i - 1 \ge 0$ . But every prime power is odd, and a product of odd numbers is odd, so the first product is odd. It is also true that p-1 is even for every prime p, and the second term is a product of even terms and thus even. So  $\phi(n)$  is the product of an even and an odd number, which is always even.

#### 1.3.2 Part 2

Suppose  $\phi(n) = 2$ . Take a prime factorization of n, so we have

$$2 = \phi(n) = \prod_{i=1}^{m} \phi(p_i^{k_i})$$
