## 1 Major Theorems

**Theorem 1** (Cauchy). For any prime p dividing the order of G, there is an element x of order p (and thus a subgroup  $H = \langle x \rangle$ ).

**Theorem 2** (Lagrange). If  $H \leq G$  is a subgroup, then  $|H| \mid |G|$ .

**Theorem 3** (Sylow 1). If  $|G| = n = \prod p_i^{a_i}$  as a prime factorization, then G has subgroups of order  $p_i^{a_i}$  for every i. Moreover, this holds for any  $1 \le r \le a_i$ .

**Theorem 4** (Classification of finitely generated abelian groups). If G is a finitely generated abelian group, then  $G \cong F \oplus T$ , where F is free abelian and T is a torsion group. If |T| = n, then  $T \cong \bigoplus \mathbb{Z}_{p_i^{\alpha_i}}$  where  $n = \prod p_i^{\alpha_i}$  is some factorization of n with the  $p_i$  not necessarily distinct.

**Theorem 5.** Conjugacy classes partition G

$$|G| = |Z(G)| + \sum_{\text{One representative in each orbit}} |C_G(g_i)| = \sum_{asdsa} [G:C(g_i)].$$

Some nice lemmas:

• Every subgroup of a cyclic group is itself cyclic.

## 2 Lecture 1 (Thu 15 Aug 2019)

We'll be using Hungerford's Algebra text. Show that a finite abelian group that is not cyclic contains a subgroup which is isomorphic

## 2.1 Definitions

The following definitions will be useful to know by heart:

- The order of a group
- Cartesian product
- Relations
- Equivalence relation
- Partition
- Binary operation
- Group
- Isomorphism
- Abelian group
- Cyclic group
- Subgroup
- Greatest common divisor
- Least common multiple
- Permutation
- Transposition
- Orbit
- Cycle
- The symmetric group  $S^n$
- The alternating group  $A_n$
- Even and odd permutations
- Cosets
- Index
- The direct product of groups
- Homomorphism
- Image of a function
- Inverse image of a function
- Kernel
- Normal subgroup
- Factor group
- Simple group

Here is a rough outline of the course:

- Group Theory
  - Groups acting on sets
  - Sylow theorems and applications
  - Classification
  - Free and free abelian groups
  - Solvable and simple groups
  - Normal series
- Galois Theory
  - Field extensions
  - Splitting fields
  - Separability
  - Finite fields
  - Cyclotomic extensions
  - Galois groups
  - Solvability by radicals
- Module theory
  - Free modules
  - Homomorphisms
  - Projective and injective modules
  - Finitely generated modules over a PID
- Linear Algebra
  - Matrices and linear transformations
  - Rank and determinants
  - Canonical forms
  - Characteristic polynomials
  - Eigenvalues and eigenvectors

#### 2.2 Preliminaries

**Definition 1.** A **group** is an ordered pair  $(G, \cdot : G \times G \to G)$  where G is a set and  $\cdot$  is a binary operation, which satisfies the following axioms:

- Associativity:  $(g_1g_2)g_3 = g_1(g_2g_3)$ ,
- Identity:  $\exists e \in G \ni ge = eg = g$ ,
- Inverses:  $g \in G \implies \exists h \in G \ni gh = gh = e$ .

#### Example 1.

- $(\mathbb{Z},+)$
- $(\mathbb{Q},+)$
- $(\mathbb{Q}^{\times}, \times)$
- $(\mathbb{R}^{\times}, \times)$
- $(GL(n, \mathbb{R}), \times) = \{A \in Mat_n \ni det(A) \neq 0\}$
- $(S_n, \circ)$

**Definition 2.** A subset  $S \subseteq G$  is a subgroup of G iff

1. 
$$s_1, s_2 \in S \implies s_1 s_2 \in S$$

$$2. \ e \in S$$

3. 
$$s \in S \implies s^{-1} \in S$$

We denote such a subgroup  $S \leq G$ .

Examples of subgroups:

- $(\mathbb{Z},+) \leq (\mathbb{Q},+)$
- $SL(n, \mathbb{R}) \leq GL(n, \mathbb{R})$ , where  $SL(n, \mathbb{R}) = \{A \in GL(n, \mathbb{R}) \ni \det(A) = 1\}$

#### 2.3 Cyclic Groups

**Definition 3.** A group G is **cyclic** iff G is generated by a single element.

**Exercise 1.** Show  $\langle g \rangle = \{ g^n \ni n \in \mathbb{Z} \} \cong \bigcap \{ H \leq G \ni g \in H \}.$ 

**Theorem 6.** Let G be a cyclic group, so  $G\langle g \rangle$ .

- If  $|G| = \infty$ , then  $G \cong \mathbb{Z}$ .
- If  $|G| = n < \infty$ , then  $G \cong \mathbb{Z}_n$ .

**Definition 4.** Let  $H \leq G$ , and define a **right coset of** G by  $aH = \{ah \ni H \in H\}$ . A similar definition can be made for **left cosets**.

Then  $aH = bH \iff b^{-1}a \in G \text{ and } Ha = Hb \iff ab^{-1} \in H.$ 

Some facts:

- Cosets partition H, i.e.  $b \notin H \implies aH \cap bH = \{e\}$ .
- |H| = |aH| = |Ha| for all  $a \in G$ .

**Theorem 7** (Lagrange). If G is a finite group and  $H \leq G$ , then  $|H| \mid |G|$ .

**Definition 5.** A subgroup  $N \leq G$  is **normal** iff gN = Ng for all  $g \in G$ , or equivalently  $gNg^{-1} \subseteq N$ . I denote this  $N \leq G$ .

When  $N \leq G$ , the set of left/right cosets of N themselves have a group structure. So we define

$$G/N = \{gN \ni g \in G\}$$
 where  $(g_1N)(g_2N) = (g_1g_2)N$ .

Given  $H, K \leq G$ , define  $HK = \{hk \ni h \in H, k \in K\}$ . We have a general formula,

$$|HK| = \frac{|H||K|}{|H \cap K|}.$$

#### 2.4 Homomorphisms

**Definition 6.** Let G, G' be groups, then  $\varphi: G \to G'$  is a homomorphism if  $\varphi(ab) = \varphi(a)\varphi(b)$ .

**Example 2.** •  $\exp: (\mathbb{R}, +) \to (\mathbb{R}^{>0}, \cdot)$  where  $\exp(a+b) = e^{a+b} = e^a e^b = \exp(a) \exp(b)$ .

- det:  $(GL(n,\mathbb{R}),\times) \to (\mathbb{R}^{\times},\times)$  where det(AB) = det(A) det(B).
- Let  $N \subseteq G$  and  $\varphi G \to G/N$  given by  $\varphi(g) = gN$ .
- Let  $\varphi: \mathbb{Z} \to \mathbb{Z}_n$  where  $\phi(g) = [g] = g \mod n$  where  $\mathbb{Z}_n \cong \mathbb{Z}/n\mathbb{Z}$

**Definition 7.** Let  $\varphi : G \to G'$ . Then  $\varphi$  is a **monomorphism** iff it is injective, an **epimorphism** iff it is surjective, and an **isomorphism** iff it is bijective.

#### 2.5 Direct Products

Let  $G_1, G_2$  be groups, then define

$$G_1 \times G_2 = \{(g_1, g_2) \ni g_1 \in G, g_2 \in G_2\}$$
 where  $(g_1, g_2)(h_1, h_2) = (g_1h_1, g_2, h_2)$ .

We have the formula  $|G_1 \times G_2| = |G_1||G_2|$ .

#### 2.6 Finitely Generated Abelian Groups

**Definition 8.** We say a group is **abelian** if G is commutative, i.e.  $g_1, g_2 \in G \implies g_1g_2 = g_2g_1$ .

**Definition 9.** A group is **finitely generated** if there exist  $\{g_1, g_2, \dots g_n\} \subseteq G$  such that  $G = \langle g_1, g_2, \dots g_n \rangle$ .

This generalizes the notion of a cyclic group, where we can simply intersect all of the subgroups that contain the  $g_i$  to define it.

We know what cyclic groups look like – they are all isomorphic to  $\mathbb{Z}$  or  $\mathbb{Z}_n$ . So now we'd like a structure theorem for abelian finitely generated groups.

**Theorem 8.** Let G be a finitely generated abelian group. Then

$$G\cong \mathbb{Z}^r\times \prod_{i=1}^s \mathbb{Z}_{p_i^{\alpha_i}}$$

for some finite  $r, s \in \mathbb{N}$  and  $p_i$  are (not necessarily distinct) primes.

**Example 3.** Let G be a finite abelian group of order 4. Then  $G \cong \mathbb{Z}_4$  or  $\mathbb{Z}_2^2$ , which are not isomorphic because every element in  $\mathbb{Z}_2^2$  has order 2 where  $\mathbb{Z}_4$  contains an element of order 4.

#### 2.7 Fundamental Homomorphism Theorem

Let  $\varphi: G \to G'$  be a group homomorphism and define  $\ker \varphi = \{g \in G \ni \varphi(g) = e'\}$ .

#### 2.7.1 The First Homomorphism Theorem

**Theorem 9.** There exists a map  $\varphi': G/\ker \varphi \to G'$  such that the following diagram commutes:

That is,  $\varphi = \varphi' \circ \eta$ , and  $\varphi'$  is an isomorphism onto its image, so  $G/\ker \varphi = \operatorname{im} \varphi$ . This map is given by  $\varphi'(g(\ker \varphi)) = \varphi(g)$ .

**Exercise 2.** Check that  $\varphi$  is well-defined.

#### 2.7.2 The Second Theorem

**Theorem 10.** Let  $K, N \leq G$  where  $N \leq G$ . Then

$$\frac{K}{N \cap K} \cong \frac{NK}{N}$$

*Proof.* Define a map  $K \xrightarrow{\varphi} NK/N$  by  $\varphi(k) = kN$ . You can show that  $\varphi$  is onto by looking at ker  $\varphi$ ; note that  $kN = \varphi(k) = N \iff k \in N$ , and so ker  $\varphi = N \cap K$ .

## 3 Lecture 2

Last time: the fundamental homomorphism theorems.

Theorem 1: Let  $\varphi: G \to G'$  be a homomorphism. Then there is a canonical homomorphism  $\eta: G \to G/\ker \varphi$  such that the usual diagram commutes. Moreover, this map induces an isomorphism  $G/\ker \varphi \cong \operatorname{im} \varphi$ .

Theorem 2: Let  $K, N \leq G$  and suppose  $N \leq G$ . Then there is an isomorphism

$$\frac{K}{K\cap N}\cong \frac{NK}{N}$$

(Show that  $K \cap N \subseteq G$ , and NK is a subgroup exactly because N is normal).

Theorem 3: Let  $H, K \subseteq G$  such that  $H \subseteq K$ .

- 1. H/K is normal in G/K.
- 2. The quotient  $(G/K)/(H/K) \cong G/H$ .

Proof: We'll use the first theorem. First make a map

$$G/K \to G/H$$
  
 $\phi(qk) = qH$ 

Exercise: Show that this map is onto, and that  $\ker \phi \cong H/K$ .

### 3.1 Permutation Groups

Let A be a set, then a permutation on A is a bijective map  $A \circlearrowleft$ . This can be made into a group with a binary operation given by composition of functions. Denote  $S_A$  the set of permutations on A.

Theorem:  $S_A$  is in fact a group. Check associativity, inverses, identity, etc.

In the special case that  $A = \{1, 2, \dots n\}$ , then  $S_n := S_A$ .

Recall two line notation

$$\begin{pmatrix} 1 & 2 & \cdots & n \\ \sigma(1) & \sigma(2) & \cdots & \sigma(n) \end{pmatrix}$$

Moreover,  $|S_n| = n!$  by a combinatorial counting argument.

Example:  $S_3$  is the symmetries of a triangle (see notes).

Example: The symmetries of a square are not given by  $S_4$ , it is instead  $D_4$  (see notes).

#### 3.2 Orbits

Permutations  $S_A$  "acts" on A, and if  $\sigma \in S_A$ , then  $\langle \sigma \rangle$  also acts on A.

Define  $a \sim b$  iff there is some n such that  $\sigma^n(a) = b$ . This is an equivalence relation, and thus induces a partition of A. See notes for diagram. The equivalence classes under this relation are called the *orbits* under  $\sigma$ .

Example:

$$\begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\ 8 & 2 & 6 & 3 & 7 & 4 & 5 & 1 \end{pmatrix} = (18)(2)(364)(57).$$

Definition: A permutation  $\sigma \in S_n$  is a *cycle* iff it contains at most one orbit with more than one element. The *length* of a cycle is the number of elements in the largest orbit.

Recall cycle notation:  $\sigma = (\sigma(1)\sigma(2)\cdots\sigma(n))$ . Note that this is read right-to-left by convention!

Theorem: Every permutation  $\sigma \in S_n$  can be written as a product of disjoint cycles.

Definition: A transposition is a cycle of length 2. Moreover, we have

and so every permutation is a product of transpositions. This is not a unique decomposition, however, as e.g.  $id = (12)^2 = (34)^2$ .

Theorem: Any  $\sigma \in S_n$  can be written as **either** an even number of transpositions or an odd number of transpositions.

Define  $A_n = \{ \sigma \in S_n \ni \sigma \text{ is even} \}.$
