1.1 Strong Linkage

We have two categories:

- $G_r T$, with a notion of *strong linkage*, and
- G_r, which instead only has *linkage*.

We'll restate a few theorems.

> **Theorem 1.1.1*(?)*.**
> Let $\lambda, \mu \in X(T)$.
>
> 1. If $[\widehat{Z}_r(\lambda) : \widehat{L}_r(\mu)]_{G_r T} \neq 0$, then $\mu \uparrow \lambda$ are strongly linked.
>
> 2. If $[Z_r(\lambda) : L_r(\mu)]_{G_r} \neq 0$, then $\mu \in W_p \cdot \lambda + p^r X(T)$.

Example 1.1.1(?): In the case of $\Phi = A_2$, we'll consider the two different categories.
We have the following picture for $\widehat{Z}$:

Figure 1: Image

Considering $X_1(T)$ and $[\widehat{Z}_1(\lambda) : \widehat{L}_1(\mu)] \neq 0$, and $\widehat{Z}_1(\lambda)$ has 6 composition factors as $G_1 T$-modules.

On the other hand, for Z, we have the following:

Figure 2: Image

This again has 6 composition factors, obtained by ??

What's the main difference?

1.2 Extensions

Let $\lambda, \mu \in X(T)$. We can use the Chevalley anti-automorphism (essentially the transpose) to obtain a form of duality for extensions:

$$\operatorname{Ext}^j_{G_rT}\left(\widehat{L}_r(\lambda), \widehat{L}_r(\mu)\right) = \operatorname{Ext}^j_{G_r}\left(\widehat{L}_r(\mu), \widehat{L}_r(\lambda)\right) \qquad \text{for } j \geq 0.$$

We have a form of a weight space decomposition

$$\operatorname{Ext}^j_{G_r}\left(L_r(\lambda), L_r(\mu)\right) = \bigoplus_{\gamma \in X(T)} \operatorname{Ext}^j_{G_r}\left(L_r(\lambda), L_r(\mu)\right)_\gamma$$

where we are taking the fixed points under the torus T action on the first factor (for which T_r acts

trivially). We can write this as

$$\cdots = \bigoplus_{\gamma \in X(T)} \mathrm{Ext}^j_{G_r} \left(L_r(\lambda), L_r(\mu) \otimes \gamma \right)$$

$$= \bigoplus_{\gamma \in X(T)} \mathrm{Ext}^j_{G_r T} \left(L_r(\lambda), L_r(\mu) \otimes p^r v \right)$$

$$= \bigoplus_{v \in X(T)} \mathrm{Ext}^j_{G_r T} \left(\widehat{L}_r(\lambda), \widehat{L}_r(\mu + p^r v) \right).$$

So if we know extensions in the G_r category, we know them in the $G_r T$ category.

There is an isomorphism

$$\mathrm{Ext}^1_{G_r T} \left(\widehat{L}_r(\lambda), \widehat{L}_r(\mu) \right) \cong \mathrm{Hom}_{G_R T} \left(\mathrm{rad}_{G_r T} \widehat{Z}_r(\lambda), \widehat{L}_r(\mu) \right).$$

Finally, for $\lambda, \mu \in X(T)$, if the above Ext^1 vanishes, then $\lambda \in W_p \cdot \mu$.
