1 Humphreys 5.3

Let λ be regular, antidominant, and integral, and suppose $M(\lambda)^n \neq 0$ but $M(\lambda)^{n+1} = 0$. In the Jantzen filtration of $M(w \cdot \lambda)$, show that $n = \ell_\lambda(w)$ where ℓ_λ is the length function of the system $(W_{[\lambda]}, \Delta_{[\lambda]})$. Thus there are $\ell(w) + 1$ nonzero layers in this filtration.

> Use 0.3(2) to describe $\Phi^+_{w \cdot \lambda}$.

2 Humphreys 7.2

Let $\mathfrak{g} = \mathfrak{sl}(2, \mathbb{C})$ and show that T^μ_λ need not take Verma modules to Verma modules.

> For example, let $\lambda = 1$ and $\mu = -3$.

2.1 Solution

Let $\lambda = 1$ and $\mu = -3$. We can then consider $\nu := \mu - \lambda = -3 - 1 = -4$, and to compute the $\bar\nu$ that appears in the definition of T^μ_λ, we consider the (usual) W-orbit of ν. In $\mathfrak{sl}(2, \mathbb{C})$, we identify $\Lambda = \mathbb{Z}$ and $s_\alpha \lambda = -\lambda$ as reflection about 0. Thus $W\nu = \{-4, 4\}$ which contains the unique dominant weight $\bar\nu = 4$. We thus have

$$T^{-3}_1(\,\cdot\,) = \mathrm{pr}_{-3}(L(4) \otimes \mathrm{pr}_1(\,\cdot\,)).$$

3 Exercise p.108

a. Work out the Jantzen filtration sections for $M(w_0 \cdot \lambda)$. List carefully any additional assumptions or facts needed to deduce $M(w_0 \cdot \lambda)^i$ uniquely.

b. Continue #4.11 for the case of singular λ, e.g. $(\lambda + \rho, \widehat{\alpha}) = 1$. If you didn't deduce the structure of all $M(w \cdot \lambda)$ there, can you complete it now?

c. Work out the non-integral case. (There are several different cases to consider.)
