Remark 1.0.1: What we've been calling a *torsor* (a sheaf with a group action plus conditions) is called by some sources a **pseudotorsor** (e.g. the Stacks Project), and what we've been calling a *locally trivial torsor* is referred to as a *torsor* instead.

Recall that statement of **??**; we'll now continue with the proof:

Proof (of Hilbert 90).

Observation 1.0.2: Let $\tau = X_{\mathrm{zar}}, X_{\mathrm{ét}}, X_{\mathrm{fppf}}$, then the data of a GL_n-torsor split by a τ-cover $U \to X$ is the same as descent data for a vector bundle relative to $U_{/X}$.

This descent data comes from the following:

$$
\begin{array}{c}
U \times_X U \\
\pi_1 \downarrow\downarrow \pi_2 \\
U \\
\downarrow \\
X
\end{array}
$$

That U trivializes our torsor means that $\pi^* T = \pi^* G$ as a G-torsor, where G acts on itself by left-multiplication. We have two different ways of pulling back, and identifications with G in both, yielding

$$
\begin{array}{ccc}
\pi_1^* \pi^* T & \xrightarrow{\sim} & \pi_2^* \pi^* T \\
\downarrow & & \downarrow \\
\pi_1^* \pi^* G & \xrightarrow{\sim} & \pi_2^* \pi^* G
\end{array}
$$

Both of the bottom objects are isomorphic to $G|_{U \times U}$.

Claim: The top horizontal map is descent data for T, and the bottom horizontal map is an automorphism of a G-torsor and thus is a section to G. I.e. a section to GL_n is an invertible matrix on double intersections (satisfying the cocycle condition) and a cover, which is precisely descent data for a vector bundle.

Using fppf descent, proved previously, we know that descent data for vector bundles is effective. So if we have a locally trivial GL_n-torsor on the fppf site, it's also trivial on the other two sites, yieldings the desired maps back and forth. Thus $H^1(X_{\mathrm{ét}}, \mathrm{GL}_n)$ is in bijection with n-dimensional vector bundles on X. ∎

Exercise 1.0.3(?): See if Hilbert 90 is true for groups other than GL_n.

1.1 Representability and Local Triviality

Question 1.1.1: Suppose G is an affine flat X-group scheme. Are all G-torsors representable by a X-scheme?

Answer 1.1.2: Yes, by the same proof as last time, try working out the details. Idea: you can trivialize a G-torsor flat locally and use fppf descent.

Question 1.1.3: Given a G-torsor T that is fppf locally trivial, is it étale locally trivial?

Answer 1.1.4: In general no, but yes if G is smooth.

> *Proof (Sketch).*
> You can take an fppf local trivialization, trivialize by p itself, then slice to get an étale trivialization. Given a torsor $T \to X$, we can base change it to itself:
>
> $$\begin{array}{ccc} T \times_X T & \longrightarrow & T \\ \Big\downarrow\Big\uparrow{\exists} & & \Big\downarrow \\ T & \longrightarrow & X \end{array}$$
>
> The torsor $T \times_X T \to T$ is trivial since there exists the indicated section. $\blacksquare$

Example 1.1.5 *(non-smooth group schemes):*
- α_p, the kernel of Frobenius on $\mathbb{A}^1$ or $\mathbb{G}_a$,
- μ_p in characteristic p, representing pth roots of unity, the kernel of Frobenius on $\mathbb{G}_m$,
- The kernel of Frobenius on any positive dimensional affine group scheme.
- $\mu_p \times \mathrm{GL}_n$, etc.
