1 Exercises

Exercise 1.1 (Gathmann 1.19)**.**
Prove that every affine variety $X \subset \mathbb{A}^n/k$ consisting of only finitely many points can be written as the zero locus of n polynomials.

Hint: Use interpolation. It is useful to assume at first that all points in X have different x_1-coordinates.

Solution:
Let $X = \{\mathbf{p}_1, \cdots, \mathbf{p}_d\} = \{\mathbf{p}_j\}_{j=1}^d$, where each $\mathbf{p}_j \in \mathbb{A}^n$ can be written in coordinates

$$\mathbf{p}_j := \left[p_j^1, p_j^2, \cdots, p_j^n \right].$$

Remark.
Proof idea: for some fixed k with $2 \leq k \leq n$, consider the pairs $(p_j^1, p_j^k) \in \mathbb{A}^2$. Letting j range over $1 \leq j \leq d$ yields d points of the form $(x, y) \in \mathbb{A}^2$, so construct an interpolating polynomial such that $f(x) = y$ for each tuple. Then $f(x) - y$ vanishes at every such tuple.

Doing this for each k (keeping the first coordinate always of the form p_j^1 and letting the second coordinate vary) yields $n - 1$ polynomials in $k[x_1, x_k] \subseteq k[x_1, \cdots, x_n]$, then adding in the polynomial $p(x) = \prod_j (x - p_j^1)$ yields a system the vanishes precisely on $\{\mathbf{p}_j\}$.

Claim: Without loss of generality, we can assume all of the first components $\left\{ p_j^1 \right\}_{j=1}^d$ are distinct.

Todo: follows from "rotation of axes"?

We will use the following fact:

Theorem 1.1 *(Lagrange).*
Given a set of d points $\{(x_i, y_i)\}_{i=1}^d$ with all x_i distinct, there exists a unique polynomial of degree d in $f \in k[x]$ such that $\tilde{f}(x_i) = y_i$ for every i.
This can be explicitly given by

$$\tilde{f}(x) = \sum_{i=1}^d y_i \left(\prod_{\substack{0 \le m \le d \\ m \ne i}} \left(\frac{x - x_m}{x_i - x_m} \right) \right).$$

Equivalently, there is a polynomial f defined by $f(x_i) = \tilde{f}(x_i) - y_i$ of degree d whose roots are precisely the x_i.

Using this theorem, we define a system of n polynomials in the following way:
- Define $f_1 \in k[x_1] \subseteq k[x_1, \cdots, x_n]$ by

$$f_1(x) = \prod_{i=1}^d \left(x - p_i^1 \right).$$

  Then the roots of f_1 are precisely the first components of the points p.

- Define $f_2 \in k[x_1, x_2] \subseteq k[x_1, \cdots, x_n]$ by considering the ordered pairs

$$\left\{ (x_1, x_2) = (p_j^1, p_j^2) \right\},$$

  then taking the unique Lagrange interpolating polynomial $\tilde{f}_2$ satisfying $\tilde{f}_2(p_j^1) = p_j^2$ for all $1 \le j \le d$. Then set $f_2 := \tilde{f}_2(x_1) - x_2 \in k[x_1, x_2]$.

- Define $f_3 \in k[x_1, x_3] \subseteq k[x_1, \cdots, x_n]$ by considering the ordered pairs

$$\left\{ (x_1, x_3) = (p_j^1, p_j^3) \right\},$$

  then taking the unique Lagrange interpolating polynomial $\tilde{f}_3$ satisfying $\tilde{f}_2(p_j^1) = p_j^3$ for all $1 \le j \le d$. Then set $f_3 := \tilde{f}_3(x_1) - x_3 \in k[x_1, x_3]$.
- $\cdots$

Continuing in this way up to $f_n \in k[x_1, x_n]$ yields a system of n polynomials.

Proposition 1.2.
$V(f_1, \cdots, f_n) = X.$

> *Proof.*
>
> **Claim:** $X \subseteq V(f_i)$:
> This is essentially by construction. Letting $p_j \in X$ be arbitrary, we find that
>
> $$f_1(p_j) = \prod_{i=1}^{d} \left(p_j^1 - p_i^1\right) = (p_j^1 - p_i^1) \prod_{\substack{i \leq d \\ i \neq j}} \left(p_j^1 - p_i^1\right) = 0.$$
>
> Similarly, for $2 \leq k \leq n$,
>
> $$f_k(p_j) = \tilde{f}_k(p_j^1) - p_j^k = 0,$$
>
> which follows from the fact that $\tilde{f}_k(p_j^1) = p_j^k$ for every k and every j by the construction
> of $\tilde{f}_k$.
>
> **Claim:** $X^c \subseteq V(f_i)^c$:
> This follows from the fact the polynomials f given by Lagrange interpolation are unique,
> and thus the roots of $\tilde{f}$ are unique. But if some other point was in $V(f_i)$, then one of its
> coordinates would be another root of some $\tilde{f}$. ∎

Exercise 1.2 (Gathmann 1.21)**.**
Determine $\sqrt{I}$ for

$$I := \left\langle x_1^3 - x_2^6, \ x_1 x_2 - x_2^3 \right\rangle \trianglelefteq \mathbb{C}[x_1, x_2].$$

> **Solution:**
> For notational purposes, let $\mathcal{I}, \mathcal{V}$ denote the maps in Hilbert's Nullstellensatz, we then have
>
> $$(\mathcal{I} \circ \mathcal{V})(I) = \sqrt{I}.$$
>
> So we consider $\mathcal{V}(I) \subseteq \mathbb{A}^2/\mathbb{C}$, the vanishing locus of these two polynomials, which yields the
> system
>
> $$\begin{cases} x^3 - y^6 & = 0 \\ xy - y^3 & = 0. \end{cases}$$
>
> In the second equation, we have $(x - y^2)y = 0$, and since $\mathbb{C}[x, y]$ is an integral domain, one
> term must be zero.
>   1. If $y = 0$, then $x^3 = 0 \implies x = 0$, and thus $(0,0) \in \mathcal{V}(I)$, i.e. the origin is contained in
>   this vanishing locus.
>   2. Otherwise, if $x - y^2 = 0$, then $x = y^2$, with no further conditions coming from the first
>   equation.

Combining these conditions,

$$P := \left\{ (t^2, t) \mid t \in \mathbb{C} \right\} \subset \mathcal{V}(I).$$

where $I = \left\langle x^3 - y^6, xy - y^3 \right\rangle$.
We have $P = \mathcal{V}(I)$, and so taking the ideal generated by P yields

$$(\mathcal{I} \circ \mathcal{V})(I) = \mathcal{I}(P) = \left\langle y - x^2 \right\rangle \in \mathbb{C}[x, y]$$

and thus $\sqrt{I} = \left\langle y - x^2 \right\rangle$.

Exercise 1.3 (Gathmann 1.22).
Let $X \subset \mathbb{A}^3/k$ be the union of the three coordinate axes. Compute generators for the ideal $I(X)$ and show that it can not be generated by fewer than 3 elements.

Solution:
Claim:

$$I(X) = \langle x_2 x_3,\ x_1 x_3,\ x_1 x_2 \rangle.$$

We can write $X = X_1 \cup X_2 \cup X_3$, where
- The x_1-axis is given by $X_1 := V(x_2 x_3) \implies I(X_1) = \langle x_2 x_3 \rangle$,
- The x_2-axis is given by $X_2 := V(x_1 x_3) \implies I(X_2) = \langle x_1 x_3 \rangle$,
- The x_3-axis is given by $X_3 := V(x_1 x_2) \implies I(X_3) = \langle x_1 x_2 \rangle$.

Here we've used, for example, that

$$I(V(x_2 x_3)) = \sqrt{\langle x_2 x_3 \rangle} = \langle x_2 x_3 \rangle$$

by applying the Nullstellensatz and noting that $\langle x_2 x_3 \rangle$ is radical since it is generated by a squarefree monomial.
We then have

$$
\begin{aligned}
I(X) &= I(X_1 \cup X_2 \cup X_3) \\
&= I(X_1) \cap I(X_2) \cap I(X_3) \\
&= \sqrt{I(X_1) + I(X_2) + I(X_3)} \\
&= \sqrt{\langle x_2, x_3 \rangle + \langle x_1 x_3 \rangle + \langle x_1 x_2 \rangle} \\
&= \sqrt{\langle x_2 x_3,\ x_1 x_3,\ x_1 x_2 \rangle} \qquad\qquad \text{since } \langle a \rangle + \langle b \rangle = \langle a, b \rangle \\
&= \langle x_2 x_3,\ x_1 x_3,\ x_1 x_2 \rangle,
\end{aligned}
$$

where in the last equality we've again used the fact that an ideal generated by squarefree monomials is radical.

Claim: $I(X)$ can not be generated by 2 or fewer elements.

Let $J := I(X)$, and toward a contradiction, suppose $J = \langle r, s \rangle$. Define $\mathfrak{m} := \langle x, y, z \rangle$ and a quotient map

$$\pi : J \longrightarrow J/\mathfrak{m}J$$

and consider the images $\pi(r), \pi(s)$.

Note that $J/\mathfrak{m}J$ is a $k[x, y, z]/\mathfrak{m}$-module, and since $k[x, y, z]/\mathfrak{m} \cong k$, it is in fact a k-vector space. Since $\pi(r), \pi(s)$ generate $J/\mathfrak{m}J$ as a k-module,

$$\dim_k J/\mathfrak{m}J \leq 2.$$

Exercise 1.4 (Gathmann 1.23: Relative Nullstellensatz)**.**
Let $Y \subset \mathbb{A}^n/k$ be an affine variety and define $A(Y)$ by the quotient

$$\pi : k[x_1, \cdots, x_n] \longrightarrow A(Y) := k[x_1, \cdots, x_n]/I(Y).$$

a. Show that $V_Y(J) = V(\pi^{-1}(J)$ for every $J \trianglelefteq A(Y)$.

b. Show that $\pi^{-1}(I_Y(X)) = I(X)$ for every affine subvariety $X \subseteq Y$.

c. Using the fact that $I(V(J)) \subset \sqrt{J}$ for every $J \trianglelefteq k[x_1, \cdots, x_n]$, deduce that $I_Y(V_Y(J)) \subset \sqrt{J}$ for every $J \trianglelefteq A(Y)$.

Conclude that there is an inclusion-reversing bijection

$$\left\{ \begin{matrix} \text{Affine subvarieties} \\ \text{of } Y \end{matrix} \right\} \iff \left\{ \begin{matrix} \text{Radical ideals} \\ \text{in } A(Y) \end{matrix} \right\}.$$

Exercise 1.5 (Extra).
Let $J \trianglelefteq k[x_1, \cdots, x_n]$ be an ideal, and find a counterexample to $I(V(J)) = \sqrt{J}$ when k is not algebraically closed.

Solution:
Take $J = \left\langle x^2 + 1 \right\rangle \trianglelefteq \mathbb{R}[x]$, noting that J is nontrivial and proper but $\mathbb{R}$ is not algebraically closed. Then $V(J) \subseteq \mathbb{R}$ is empty, and thus $I(V(J)) = I(\emptyset)$.

Claim: $I(V(J)) = \mathbb{R}[x]$.
Checking definitions, for any set $X \subset \mathbb{A}^n/k$ we have

$$I(X) = \left\{ f \in \mathbb{R}[x] \ \middle| \ \forall x \in X, \ f(x) = 0 \right\}$$

and so we vacuously have

$$I(\emptyset) = \left\{ f \in \mathbb{R}[x] \ \middle| \ \forall x \in \emptyset, \ f(x) = 0 \right\} = \{ f \in \mathbb{R}[x] \} = \mathbb{R}[x].$$

Claim: $\sqrt{J} \neq \mathbb{R}[x]$.
This follows from the fact that maximal ideals are radical, and $\mathbb{R}[x]/J \cong \mathbb{C}$ being a field implies that J is maximal. In this case $\sqrt{J} = J \neq \mathbb{R}[x]$.

That maximal ideals are radical follows from the fact that if $J \trianglelefteq R$ is maximal, we have $J \subset \sqrt{J} \subset R$ which forces $\sqrt{J} = J$ or $\sqrt{J} = R$.

But if $\sqrt{J} = R$, then

$$1 \in \sqrt{J} \implies 1^n \in J \text{ for some } n \implies 1 \in J \implies J = R,$$

contradicting the assumption that J is maximal and thus proper by definition.
